Section 7. Contact Recreation Use Support Determination

The Idaho water quality standards provide for water bodies to be designated for either primary or secondary contact recreation use. Primary contact recreation is often considered the "swimmable" goal of the CWA where there is a moderate to high probability of prolonged and intimate contact by humans. Primary contact recreation activities include swimming, water skiing, or skin diving where ingestion of small quantities of water is likely to occur. Secondary contact recreation is often considered recreation "on" or "about" the water. These recreation activities may include fishing, boating, wading, infrequent swimming, and other activities where ingestion of raw water is not likely to occur.

7.1. Recreation Criteria Evaluation Policy

DEQ evaluates recreation criteria using data that are less than five years old. For narrative criteria, DEQ investigates beach or swimming closures occurring in the last five years to identify potential exceedances. If two or more closures indicate bacteria or toxic substance causes, then DEQ concludes the water body is not fully supporting. Figure 7-1 illustrates the use determination process for contact recreation. DEQ also evaluates other evidence that indicates an exceedance of numeric criteria. For toxic substances criteria, DEQ concludes not fully supporting if there are any exceedances of toxic substance criteria as specified in WQS § 210.01-02 (See Figure 7-1).

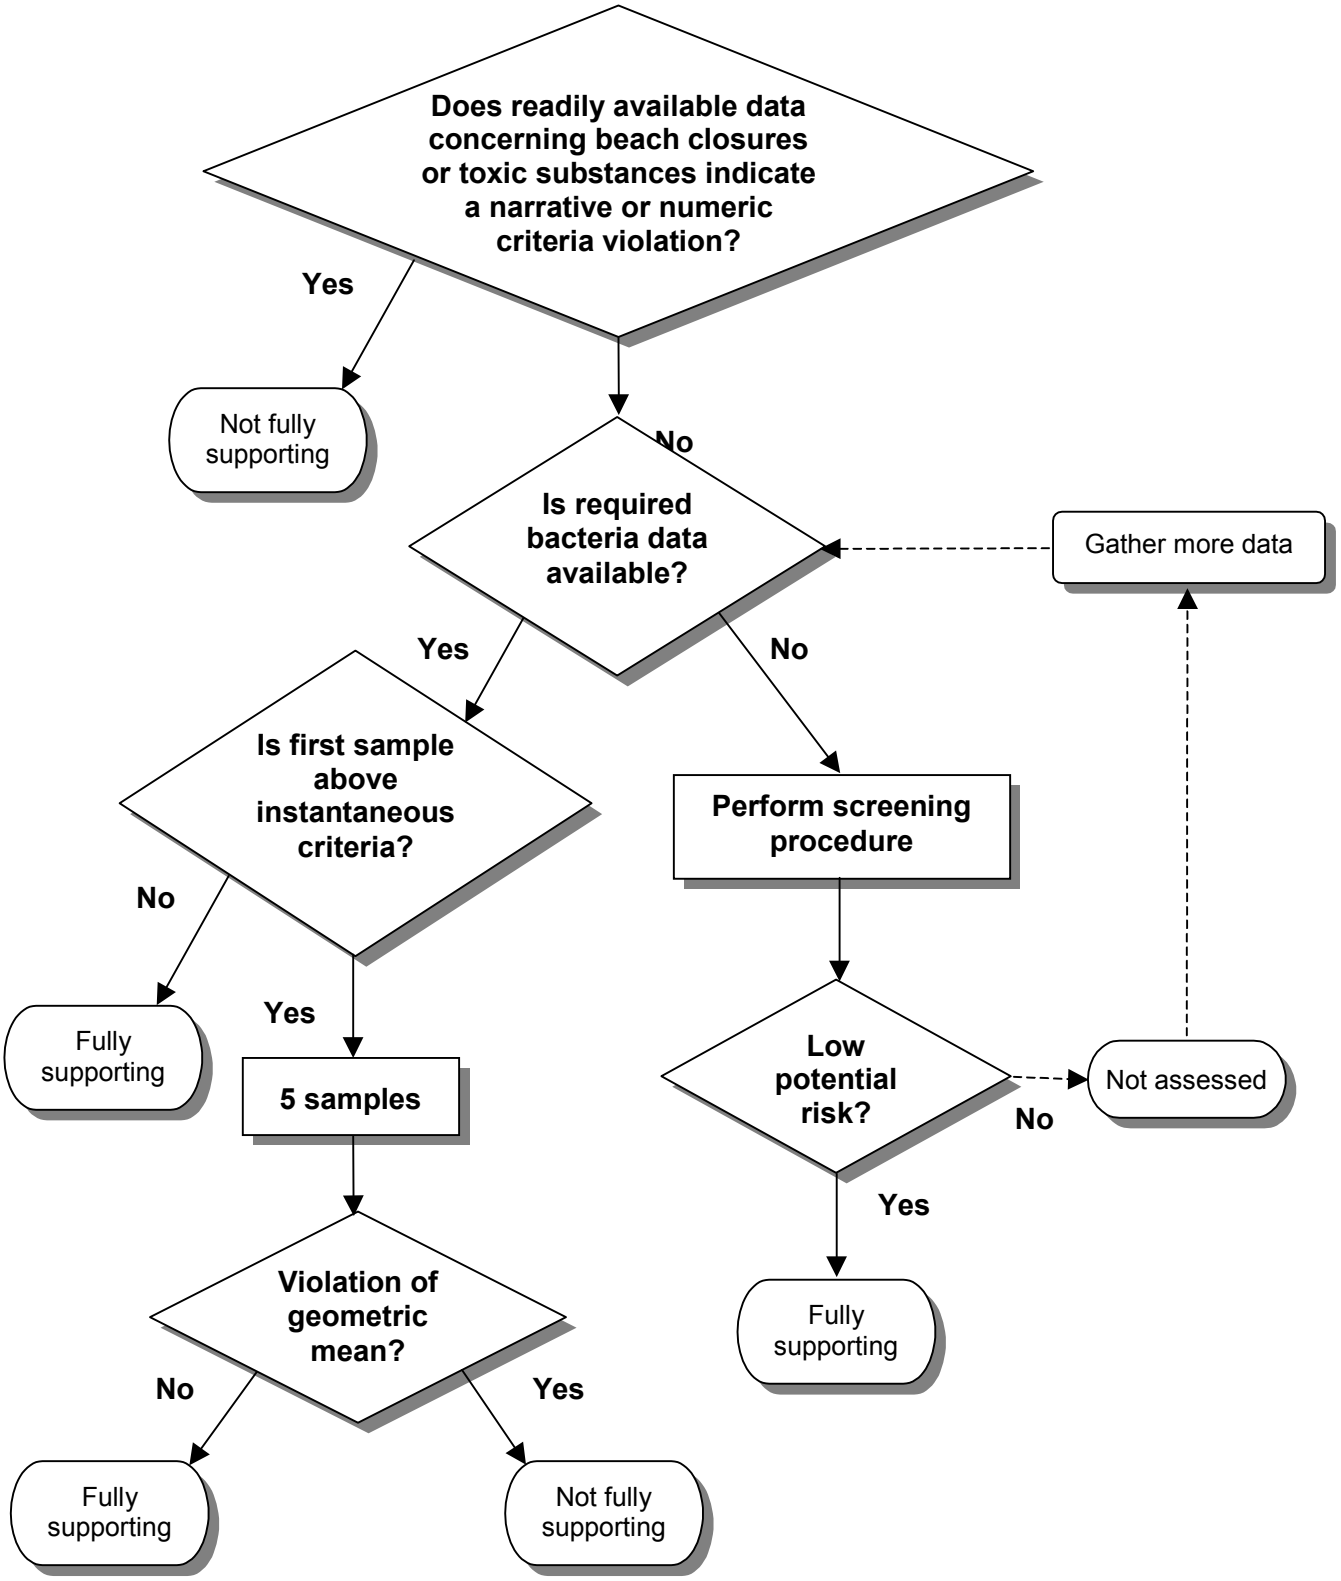

Figure 7-1. Contact Recreation Use Support Determination

7.2. Bacteria Data

The numeric bacteria criterion for an exceedance is the same for primary and secondary contact recreation. The *E. coli* bacteria count must exceed 125 organisms per 100 ml geometric mean (five samples within 30 days). However, the instantaneous criterion to trigger additional sampling is different for primary and secondary contact recreation. The *E. coli* bacteria count must exceed 406 organisms per 100 ml for primary contact and 576 organisms per 100 ml for secondary contact (WQS § 251.01).

The assessor first evaluates if instantaneous criteria indicate requirements for additional sampling. If not, then the water body is fully supporting. If so, then DEQ assesses the geometric mean results from five samples to determine support status. If the required additional sampling results are not available, then the water body is determined not assessed (NA) until sampling results permit an assessment. If bacteria data are not available for the water body, then DEQ will use a bacteria-screening procedure.

If instantaneous bacteria criteria do not indicate requirements for additional sampling, then DEQ determines the use support is fully supporting.

If the geometric mean of the bacteria samples does not indicate a numeric criteria exceedance, then DEQ determines the use support is fully supporting.

If the geometric mean of the bacteria samples indicates a numeric criteria exceedance, then DEQ determines the use support is not fully supporting.

If data are not available, then DEQ uses the bacteria screening procedure.

7.3. Bacteria Screening Procedure Policy

This procedure is used when current bacteria, toxic substances and/or narrative data do not exist for the water body. BURP also incorporates this procedure to guide monitoring procedures for bacteria.

DEQ uses GIS capabilities and local knowledge to determine if upstream land uses have the potential for increasing bacteria concentrations in the water body. Activities that could affect the reach include agriculture, grazing, urban or housing development, wastewater treatment facilities, or septic tanks. If there is a low potential risk, then the water body is considered fully supporting for recreation. If there is a moderate to high potential risk, then the water body is determined not assessed and additional data is gathered. The level of potential risk is based on the best professional judgment of the assessor. Bacteria data are collected during the required index period to permit a later assessment.

If there is a low potential risk for a numeric criteria exceedance, then DEQ presumes the use support is fully supporting.

If there is a moderate to high potential risk for a numeric criteria exceedance, then DEQ identifies the water body as not assessed and gathers necessary data.

Section 8. Water Supply Use Support Determination

8.1. Domestic Water Supply (Drinking Water)

There are presently over 2,100 public water supply systems in Idaho, 80 percent of which serve 500 or fewer people (Idaho Wellhead Protection Plan 1997). In Idaho, 90 percent of drinking water comes from ground water, and only 10 percent is supplied by surface water. Public water systems supplied by surface water are generally located in northern Idaho; however, there are some systems in southern Idaho. The water quality standards (WQS 252.01.b.i.) list the present small drinking water systems supplied by surface water. The assessor will coordinate with the DEQ regional office drinking water program to determine if a particular water body supplies a public water system and identify any numeric criteria exceedances of the ambient surface water quality standards for water supply (WQS § 252). These standards principally address turbidity criteria.

The assessor will also coordinate with the DEQ source water assessment program to identify potential contaminant threats to public drinking water systems due to impaired surface water quality. The source water assessments include delineating the source water assessment area, inventorying potential contaminants within the delineated area, and conducting a susceptibility analysis of the potential contaminants (DEQ 1999).

The source water assessment results are compiled in a report that includes any violations of drinking water standards. The DEQ assessor will coordinate with the source water assessment program and review these reports to identify any numeric criteria exceedances of the surface water quality standards for water supplies. DEQ also will review any additional data supplied by third parties for numeric criteria exceedances.

DEQ will take the following steps to make a use support determination for domestic water supply:

If there are numeric criteria exceedances of the ambient surface water quality standards for water supply (IDAPA 210), then the water body is not fully supporting.

Unless there is evidence to the contrary, DEQ will presume use support of domestic water supply is fully supporting.

8.2. Agricultural and Industrial Water Supply

Generally, DEQ considers agricultural and industrial water supplies fully supporting although violations of narrative criteria might occur. However, excessive nutrients or toxic contaminants might result in a not fully supporting determination. The assessor should refer to WQS § 252.02-03 and provide a documented rationale for a not fully supporting determination. Collection of additional data to support such a determination is recommended.

Unless there is evidence to the contrary, DEQ will presume use support of agricultural and industrial water supply is fully supporting.

Section 9. Wildlife Habitat and Aesthetics Use Support Determination

Wildlife habitat and aesthetics are designated uses for all surface waters of Idaho. Unless there is evidence to the contrary, DEQ policy is to determine these uses are fully supporting. Evidence to the contrary would likely occur through a public forum or from documentation submitted by wildlife experts (e.g., IDFG, U.S. Fish and Wildlife Service, universities, etc.).

Unless there is evidence to the contrary, DEQ presumes support use of wildlife habitat and aesthetics are fully supporting.

Section 10. Assessment Examples

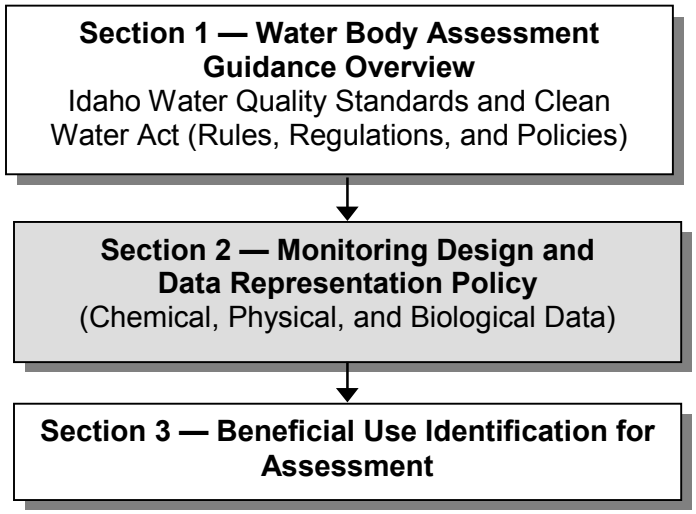
The following examples describe the application of the WBAG using actual data collected from Idaho streams. The steps shown here follow the sequence of WBAG sections. The results and conclusions explained in this section are for example purposes only. For this illustration, DEQ has informally attempted to obtain outside data in addition to BURP data. However, additional information could be supplied as a result of a formal 303(d)/305(b) request for data that might support or change the beneficial use results described here for these stream examples.

10.1. Example 1 - Big Cottonwood Creek

The Big Cottonwood Creek example illustrates using BURP data only in the assessment process. In the past, a majority of the assessments have fallen into this category.

10.1.1. Water Body Identification and Stratification

Please see Figure 1-2 to become familiar with the sequence of the WBAG sections that lead to a beneficial use support or non-support determination. The initial three sections of the WBAG sequence are as follows:



The first step in the assessment process is to identify the location of the water body and stratify it into groups for assessment purposes. Big Cottonwood Creek is approximately 21 miles long and a second order stream located in the Goose Creek HUC #17040211 (see Figures 10-1 and 10-2). The shrubland watershed

has a road crossing at the BURP site and is used for both recreation and grazing purposes. USFS and IDFG have retired the grazing allotments along the lower portion of Big Cottonwood Creek. After Big Cottonwood Creek leaves BLM public lands it is diverted for agricultural uses and flows only occasionally in its natural channel.

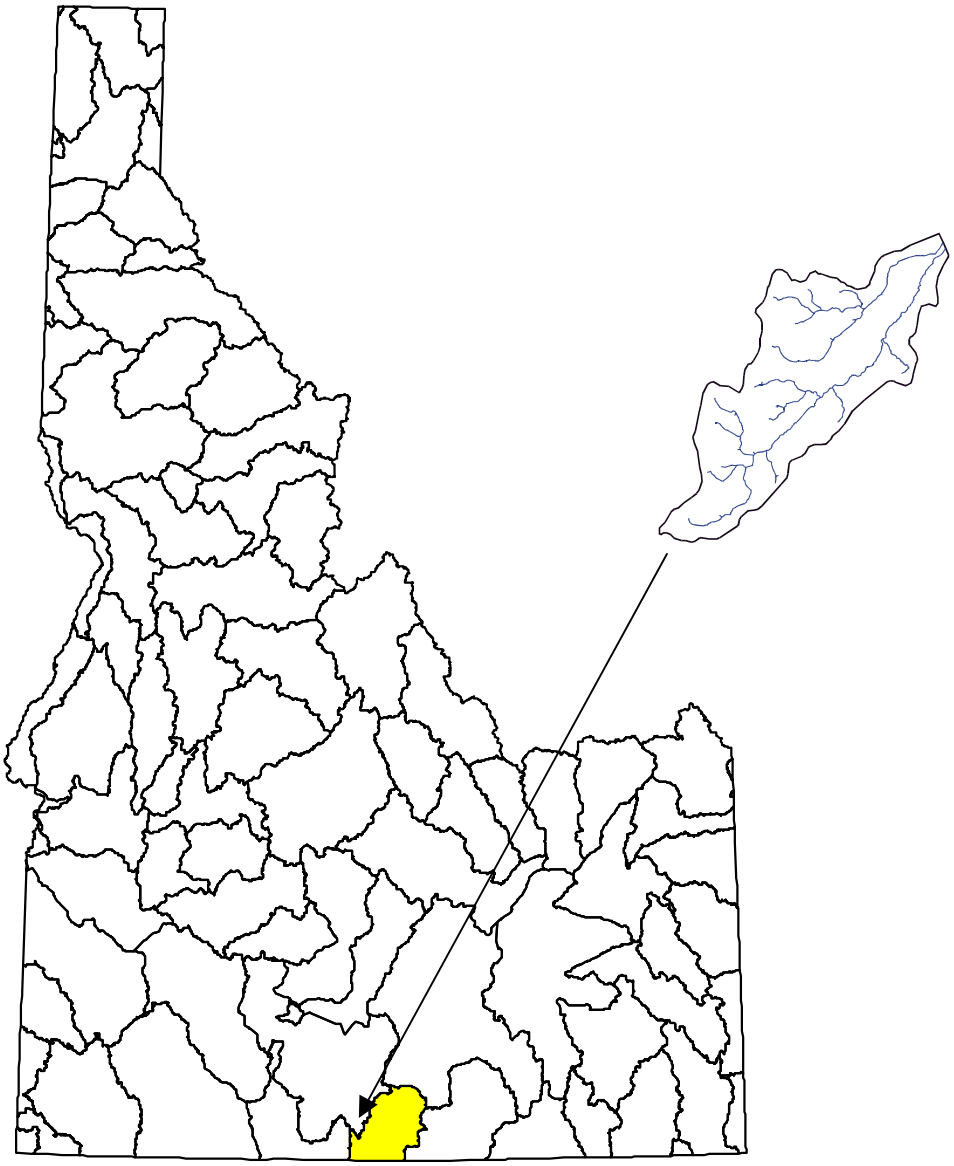


Figure 10-1. Big Cottonwood Creek located in Goose Creek HUC #17040211

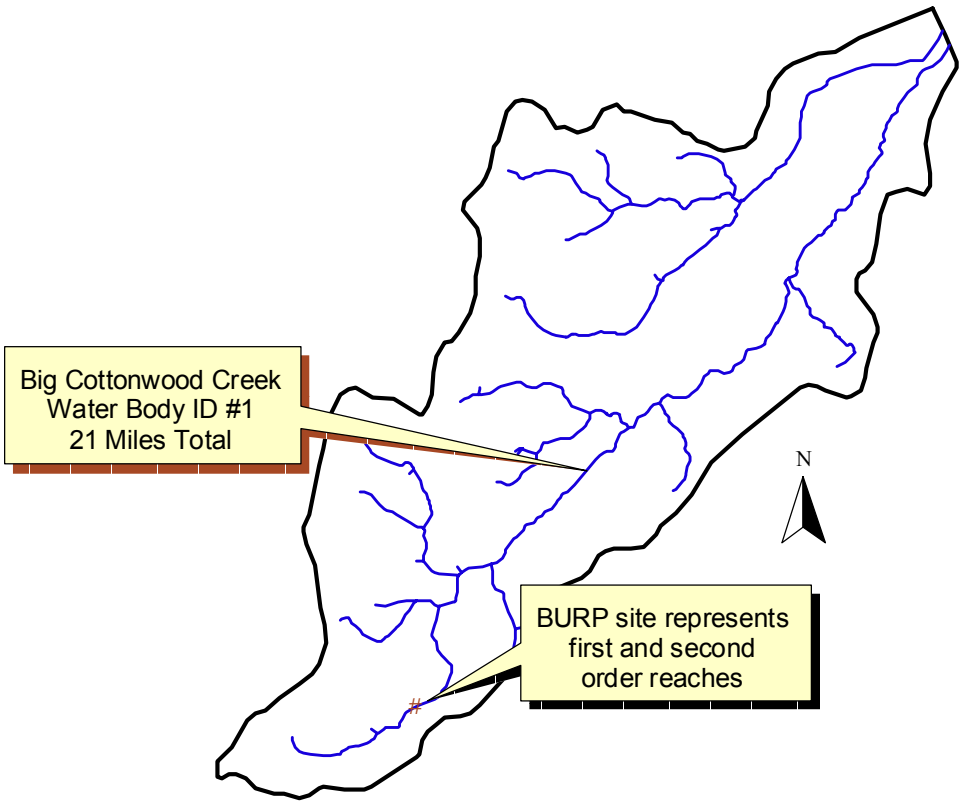

Figure 10-2. Big Cottonwood Creek in 6th Field HUC #170402111901. BURP site at upper portion of watershed

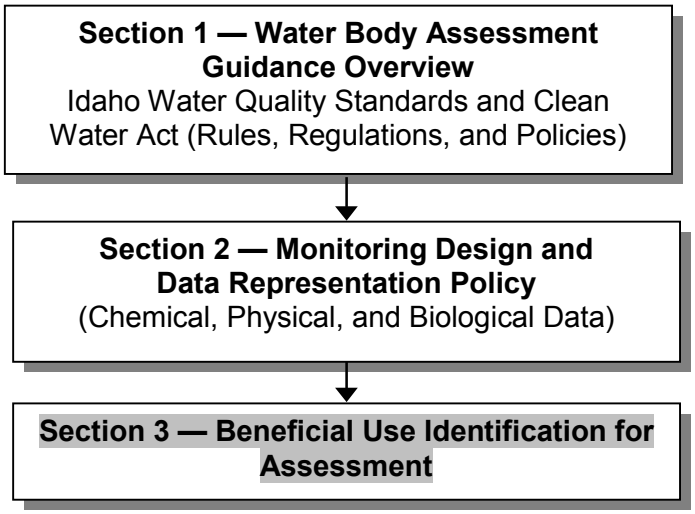
10.1.2. Water Body Size Determination

The second step in the WBAG process is to determine the water body size and whether it is a stream or river. DEQ uses different bioassessment indexes to make this determination (see Section 2). After identifying values and an average criteria rating for the water body size criteria, the assessor determines the average rating is less than 1.7 and consequently, classifies Big Cottonwood Creek as a stream. Table 10-1 summarizes the results of the water body size determination.

Table 10-1. Summary of water body size criteria results

Criteria	Value	Rating
Stream order	3.00	1
Average width at base flow (m)	1.85	1
Average depth at base flow (m)	0.16	1
	Average Rating	1

10.1.3. Identification of Beneficial Uses for Assessment

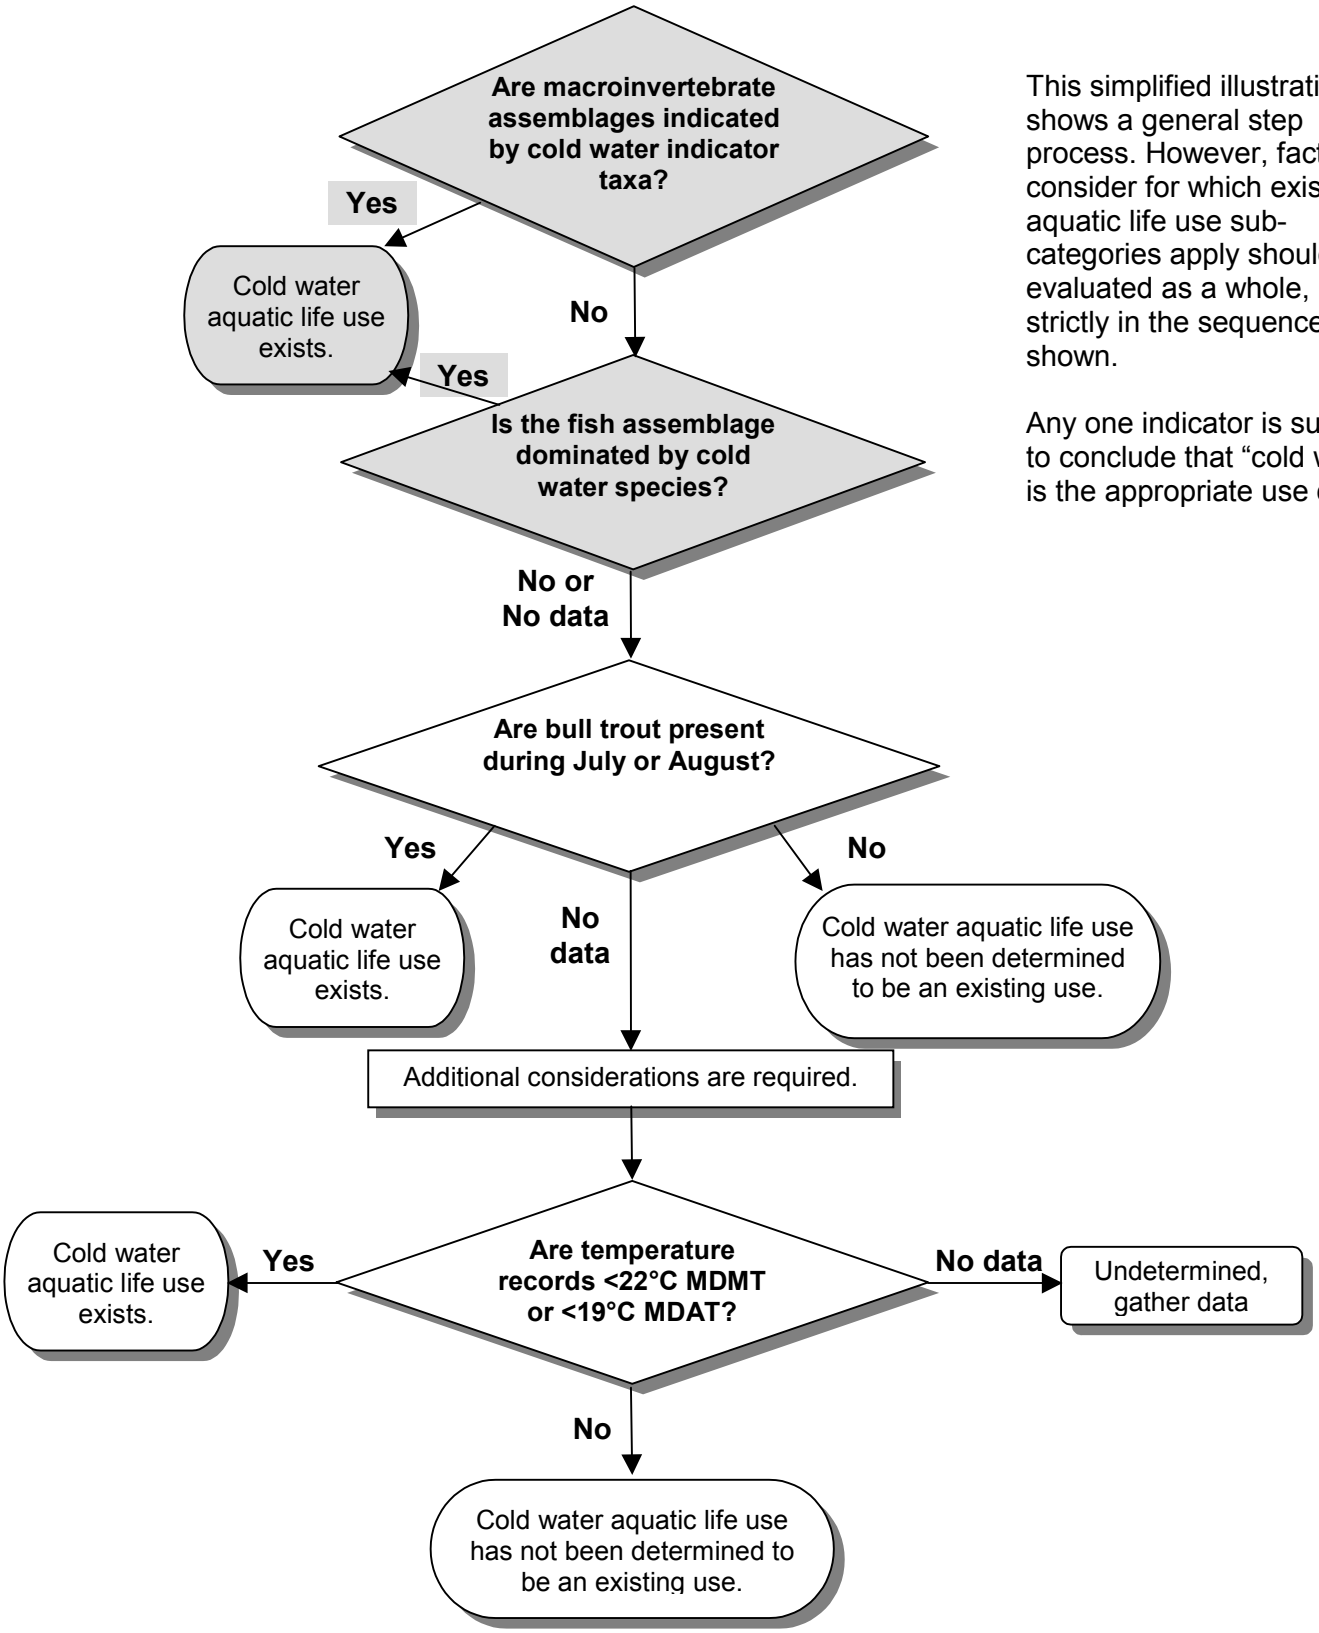


Before assessing the water body, the assessor must first determine which beneficial uses to assess. Surface water use designations are defined and listed in the Idaho water quality standards (WQS § 100-160). These include uses that are applied specifically to a water body (aquatic life, recreation, domestic water supply), and uses that are applied to all waters of the state (agricultural and industrial water supply, wildlife habitat, and aesthetics). Water bodies with specific use designations are identified in WQS § 110-160.

In this example, Big Cottonwood Creek has not been designated for aquatic life or contact recreation uses. Sampling of the creek identified the presence of cold water indicator taxa (see Table 10-2, Section 3.2.2.1, and Appendix A) and a dominance of cutthroat trout (cold water species). Using this information and the guidance from Section 3, the cold water aquatic life beneficial use was identified for assessment purposes (see Figure 10-3). Since the sample was comprised of many individuals measuring less than 100 mm, salmonid spawning was also identified as a beneficial use. Lastly, primary contact recreation was selected as an assessment use since this stream is accessible and used heavily for recreational purposes.

Table 10-2. Cold water indicator taxa found in Big Cottonwood Creek sample

ORDER	Genus/Species	Temperature Preference
Coleoptera		
	Narpus sp.	12.58
Ephemeroptera		
	Baetis bicaudatus	8.76
	Cinygmula sp.	10.31
	Drunella doddsi	10.47
Plecoptera		
	Cultus sp.	11.04
	Leuctridae	9.43
	Paraperla sp.	9.32
	Perlidae	11.26
	Sweltsa sp.	11.45
Trichoptera		
	Apatania sp.	11.04
	Parapsyche elsis	9.47
	Rhyacophila brunnea gr.	10.56



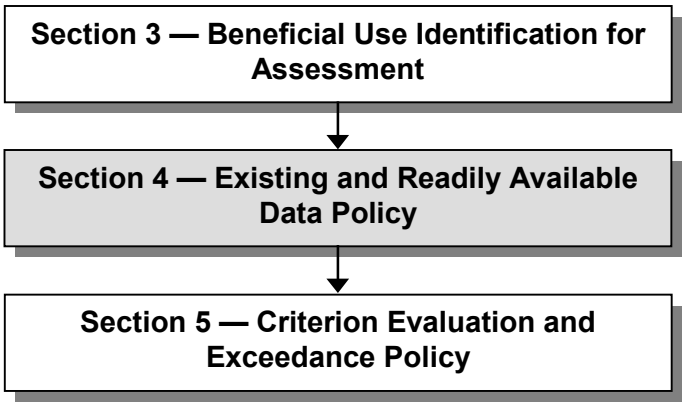
This simplified illustration shows a general step process. However, factors to consider for which existing aquatic life use sub-categories apply should be evaluated as a whole, not strictly in the sequence shown.

Any one indicator is sufficient to conclude that "cold water" is the appropriate use class.

Figure 10-3. Identification of Beneficial Uses for Big Cottonwood Creek

10.1.4. Evaluation of Existing and Readily Available Data

The next step is to evaluate existing and readily available data according to policies described in Section 4 and illustrated in Figure 4-2.



Macroinvertebrate, fish, and habitat data were collected at one BURP site for this assessment unit. Due to heavy recreational uses on this stream, DEQ also collected bacteria samples to assess the primary contact beneficial use.

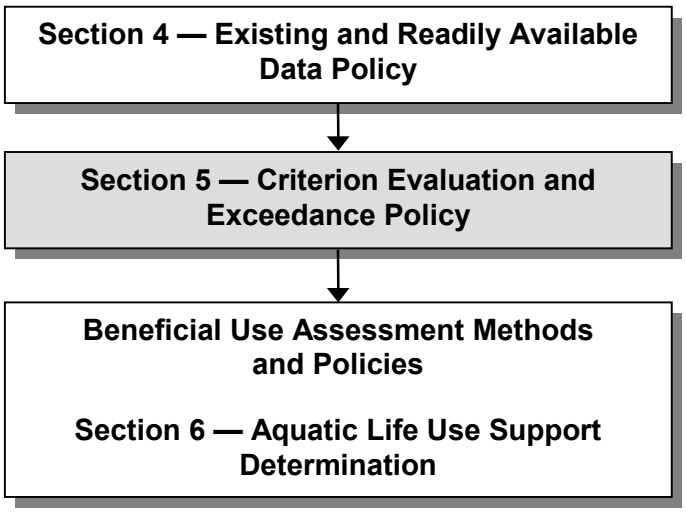
All the data was collected using BURP protocols and consequently are evaluated as Tier I and BURP compatible (see Table 10-3). The macroinvertebrate, fish and habitat data types are run through the appropriate DEQ multimetric indexes for data integration and ALUS preliminary determinations.

Table 10-3. Summary of data evaluation for Big Cottonwood Creek

Data Type (Source)	Tier	BURP compatible?	Associated with numeric criteria?	Analysis and conclusions reached?	Action
Macroinvertebrate (DEQ)	I	Yes	No	No	Calculate SMI score and assess according to Section 6.
Fish (DEQ)	I	Yes	No	No	Calculate SFI score and assess according to Section 6.
Habitat (DEQ)	I	Yes	No	No	Calculate SHI score and assess according to Section 6.
Bacteria (DEQ)	I	Yes	Yes	No	Assess according to Section 7.

10.1.5. Criterion Exceedance Evaluation

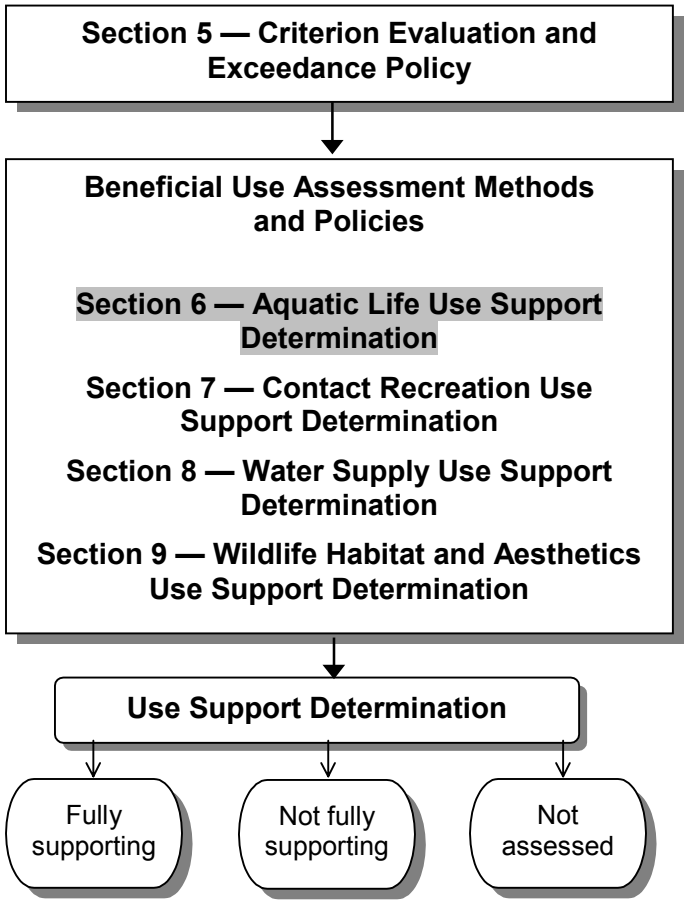
After evaluating the existing and readily available data, the next step is to ensure that the narrative and numeric criteria policies, as described in Section 5, are taken into consideration during beneficial use assessments.



DEQ assesses narrative and numeric criteria for each beneficial use, beginning with aquatic life use support determinations, and ascertains their effect on the support status determinations. For narrative criteria, DEQ depends largely on biological data to interpret impacts to the beneficial use. Sections 4.3 and 5.1 describe policies concerning use of other data types to interpret narrative criteria. For this example, DEQ will interpret narrative criteria using biological data as applied in Section 6. Other than bacteria data, DEQ is not aware of any other data collected that was associated with numeric criteria.

10.1.6. Aquatic Life Use Support Determination

The aquatic life use support determination involves making a support/non-support determination for cold water aquatic life uses as well as salmonid spawning uses. The processes for making these determinations follow.



10.1.6.1. ALUS Determination for Cold Water Aquatic Life

The assessor calculates the stream index for the macroinvertebrate, fish, and habitat BURP data. Table 10-4 summarizes the index calculations for the available BURP compatible data. The assessor then assigns condition ratings to each index score for data integration purposes. In assigning these ratings, the assessor uses the following classifications: basins (Table 6-1, SMI), range (Table 6-2 SFI), and Snake River Basin/High Desert (Table 6-3 SHI) classifications. These corresponding condition ratings are also shown in Table 10-4.

Table 10-4. Stream index scores and corresponding condition ratings for Big Cottonwood Creek

Monitoring Station	SMI Score	SMI Condition Rating	SFI Score	SFI Condition Rating	SHI Score	SHI Condition Rating	Condition Rating Average
Site	87	3	79	2	82	3	2.67

DEQ averages the condition ratings to integrate the different index scores. The result for Big Cottonwood Creek is 2.67. If there had been two BURP sites, DEQ uses the lower average of the condition ratings. If there had been more than two monitoring sites, then DEQ takes an average of all the condition ratings.

The assessor is now ready to make a preliminary ALUS determination. There are no numeric criteria exceedances (see Section 10.1.4) or index scores below the minimum threshold breakpoints (see Table 10-4 and the corresponding threshold tables in Section 6). The average condition rating for the stream index scores greater than 2.0 resulting in a fully supporting preliminary determination. Figure 10-4 depicts this decision process.

10.1.6.2. ALUS Determination for Salmonid Spawning

DEQ evaluates salmonid spawning within the context of the ALUS determination and applicable numeric criteria through a two-step process. First, the assessor uses the preliminary ALUS determination. This determination is considered to be the same for cold water aquatic life and salmonid spawning before applicable numeric criteria are applied. Consequently, the preliminary salmonid spawning determination is fully supporting.

Next, the assessor determines if a numeric criteria violation has occurred specific to salmonid spawning (see WQS § 250.02.3, Section 5.2.4., and Section 6.5.2). Since there was no data associated with salmonid spawning numeric criteria, salmonid spawning does not require further assessment and is determined fully supporting. Figure 10-5 depicts this decision process.

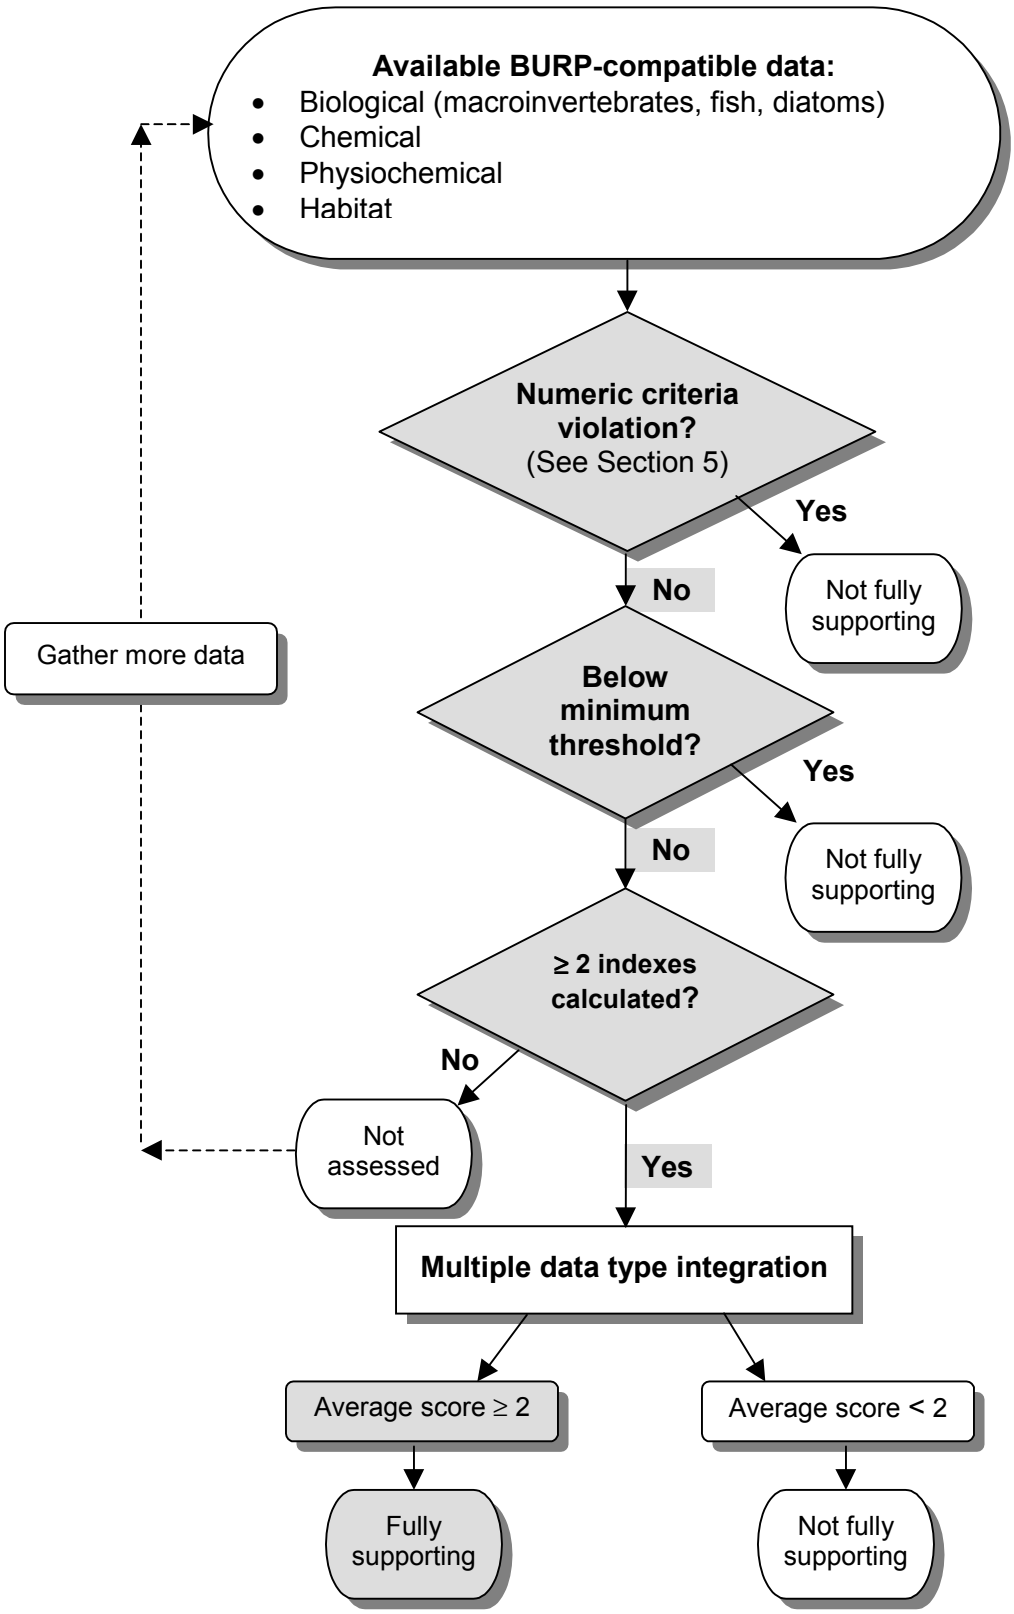


Figure 10-4. Stream cold water aquatic life use support determination for Big Cottonwood Creek

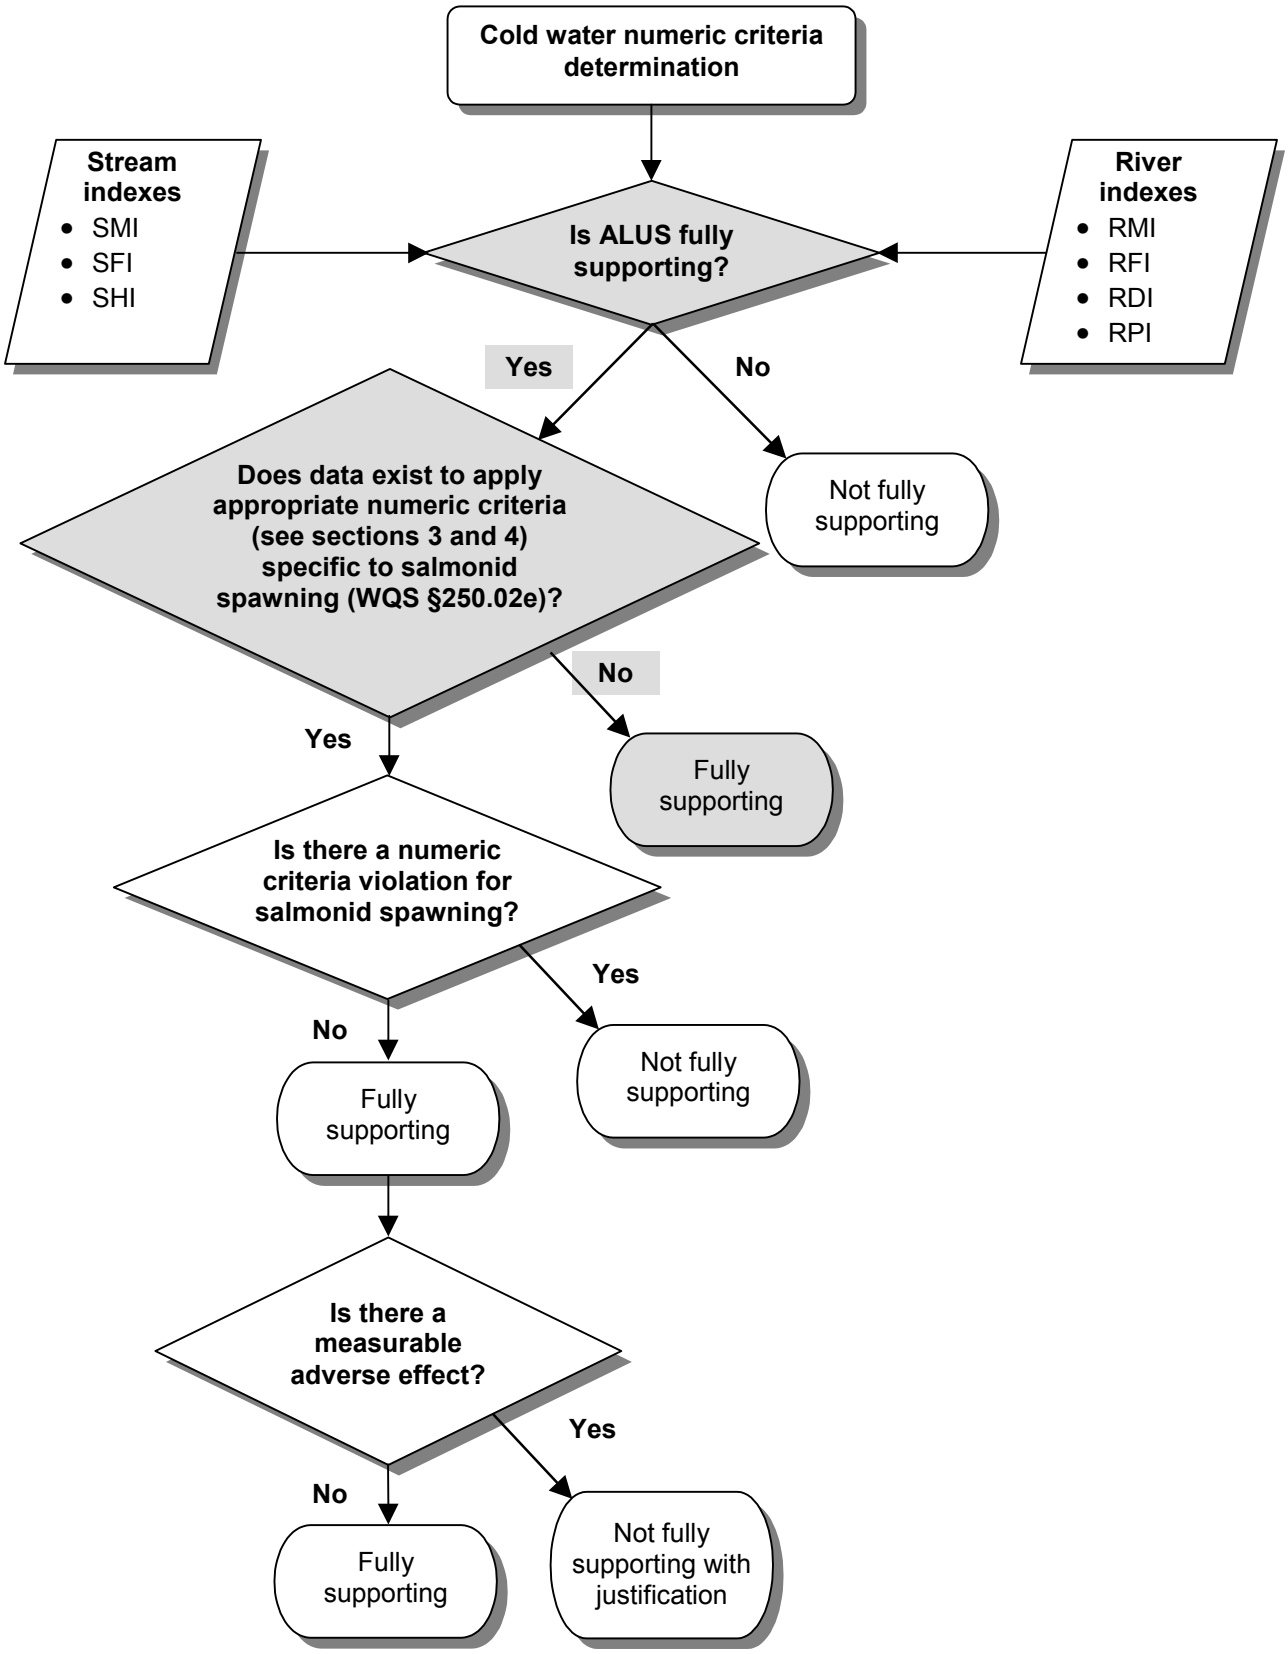

Figure 10-5. Stream salmonid spawning use support determination for Big Cottonwood Creek

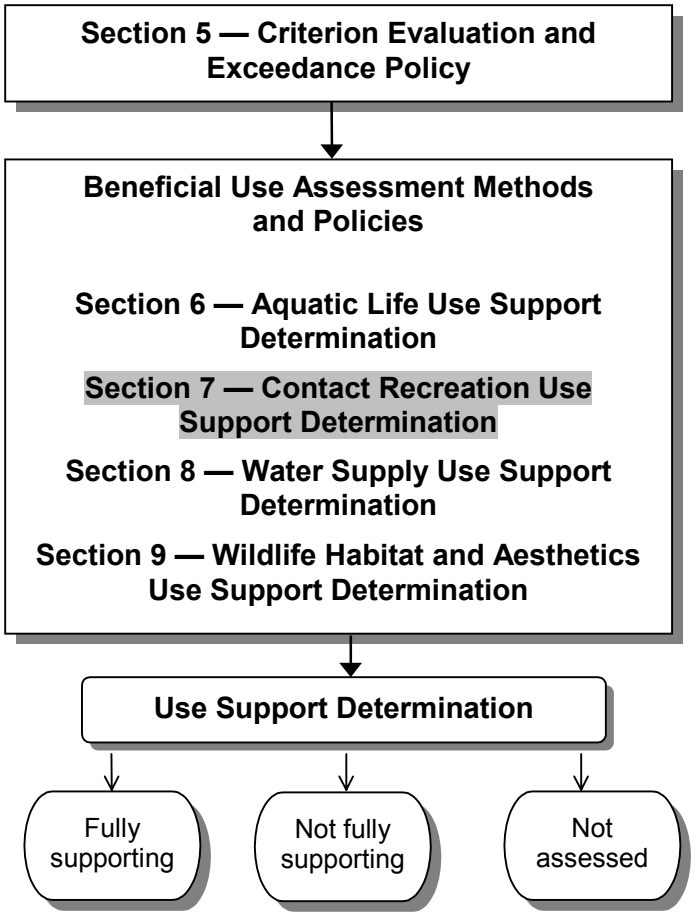
10.1.7. Contact Recreation Use Support Determination



To determine the support status of contact recreation, DEQ normally assesses bacteria data. There may be cases where other data apply (see Section 7.2.). For this example, the bacteria data did not indicate any exceedance of the numeric criteria standard. Specifically, the grab sample was 40 *E. coli* colonies per 100 ml and considerably less than the primary contact instantaneous stream criteria of 406 *E. coli* per 100 ml. Therefore, primary contact recreation is fully supporting. Figure 10-6 depicts this decision process.

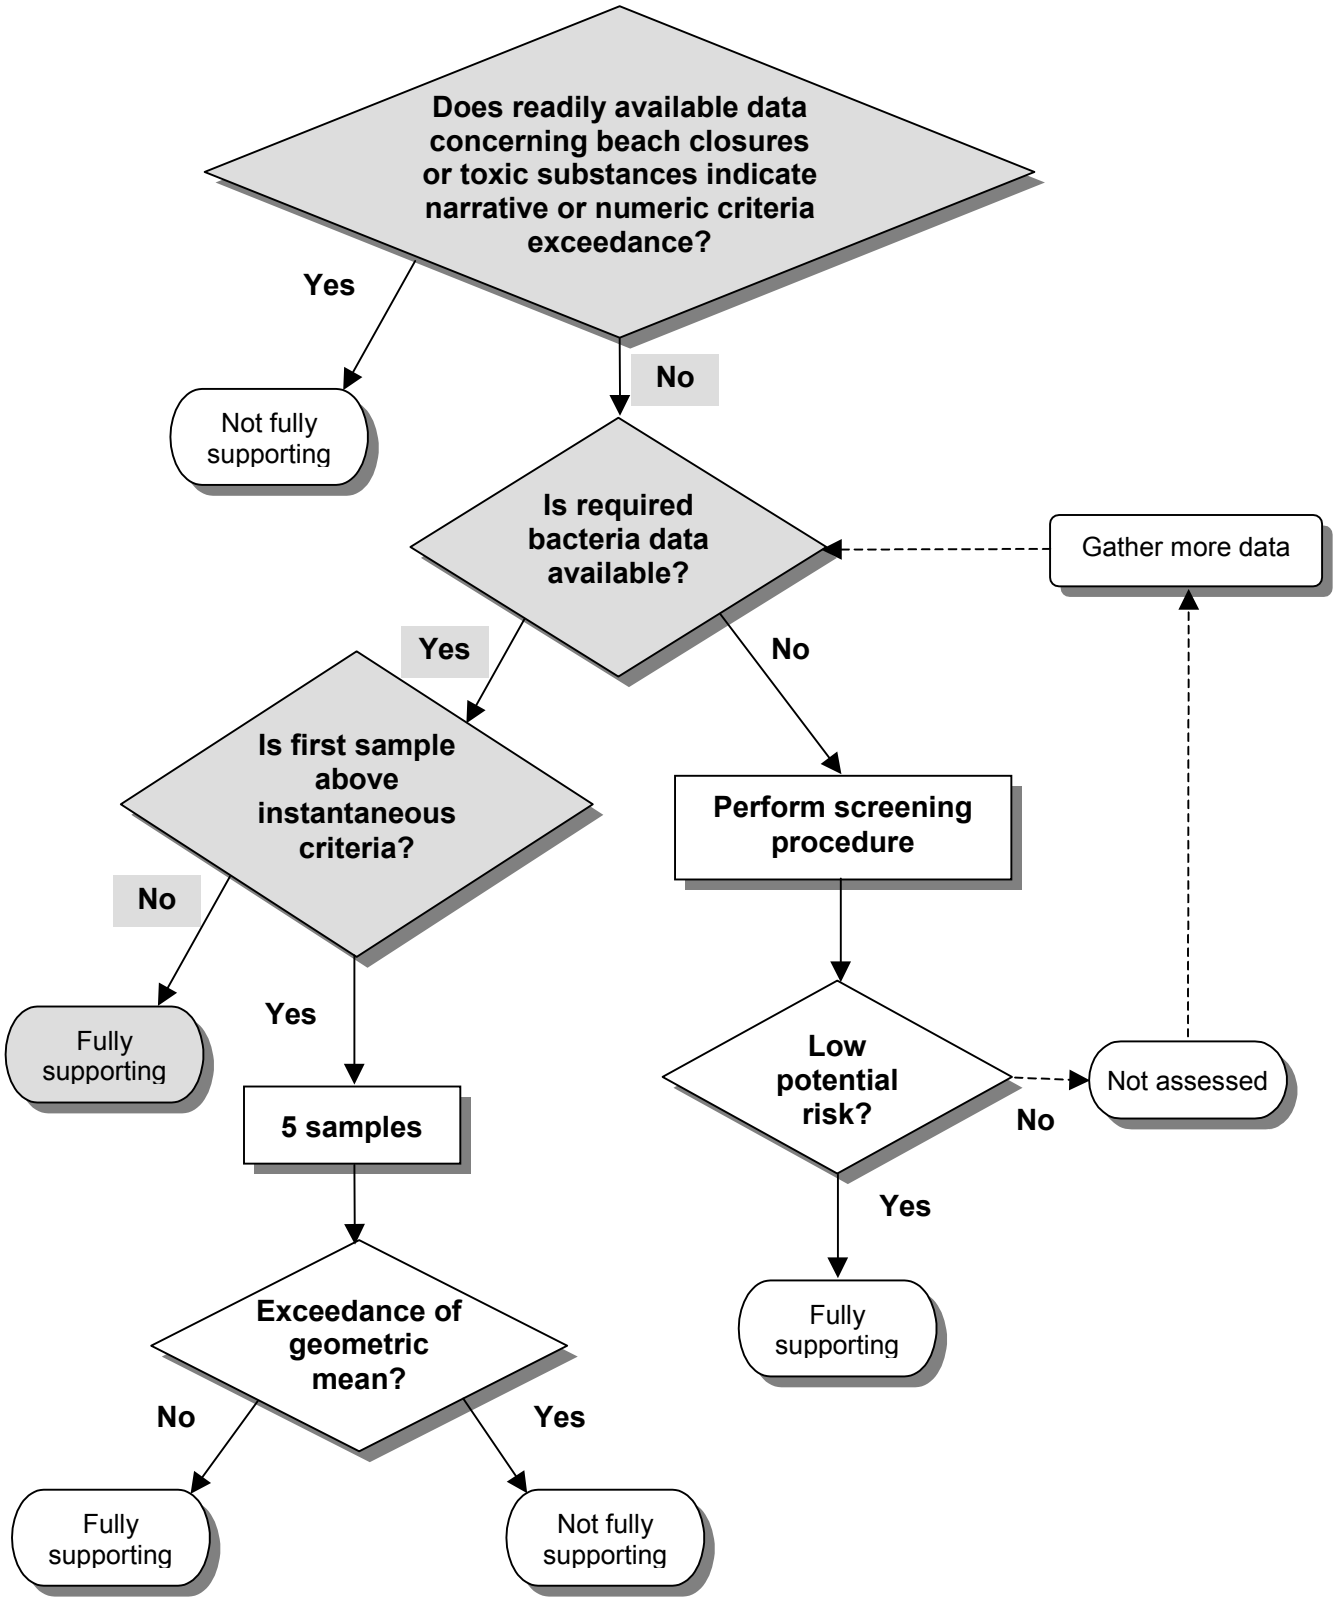


Figure 10-6. Contact recreation use support determination for Big Cottonwood Creek

10.1.8. Summary of Beneficial Use Support Determinations for Big Cottonwood Creek

Sections 8 and 9 address the other beneficial uses. At this time, DEQ policy is to assume these uses are fully supporting unless there is evidence to the contrary. For this example, there was no evidence to the contrary for these beneficial uses. Table 10-5 summarizes the assessment results of Big Cottonwood Creek which is determined to be fully supporting.

Table 10-5. Summary of beneficial use support determinations for Big Cottonwood Creek

Beneficial Use	Support Determination	Basis for Determination
Aquatic Life	Fully Supporting	Index data integration indicates fully supporting.
Contact Recreation	Fully Supporting	Bacteria results.
Water Supply, Wildlife Habitat, and Aesthetics	Fully Supporting	No evidence to the contrary and policy.

10.2. Example 2 - Deer Creek

10.2.1. Water Body Identification and Stratification

Deer Creek is a third order stream located in the Bruneau River HUC #17050102 (see Figure 10-7). This water body originates in Nevada and flows approximately 8.7 miles in Idaho (see Figure 10-8). The assessment unit for this example is located about one mile above Three Creek Road in a shallow canyon. The watershed is mainly shrubland and the major land use in this area is grazing with limited recreation. The creek is diverted below the BURP site and becomes intermittent especially during the summer months.

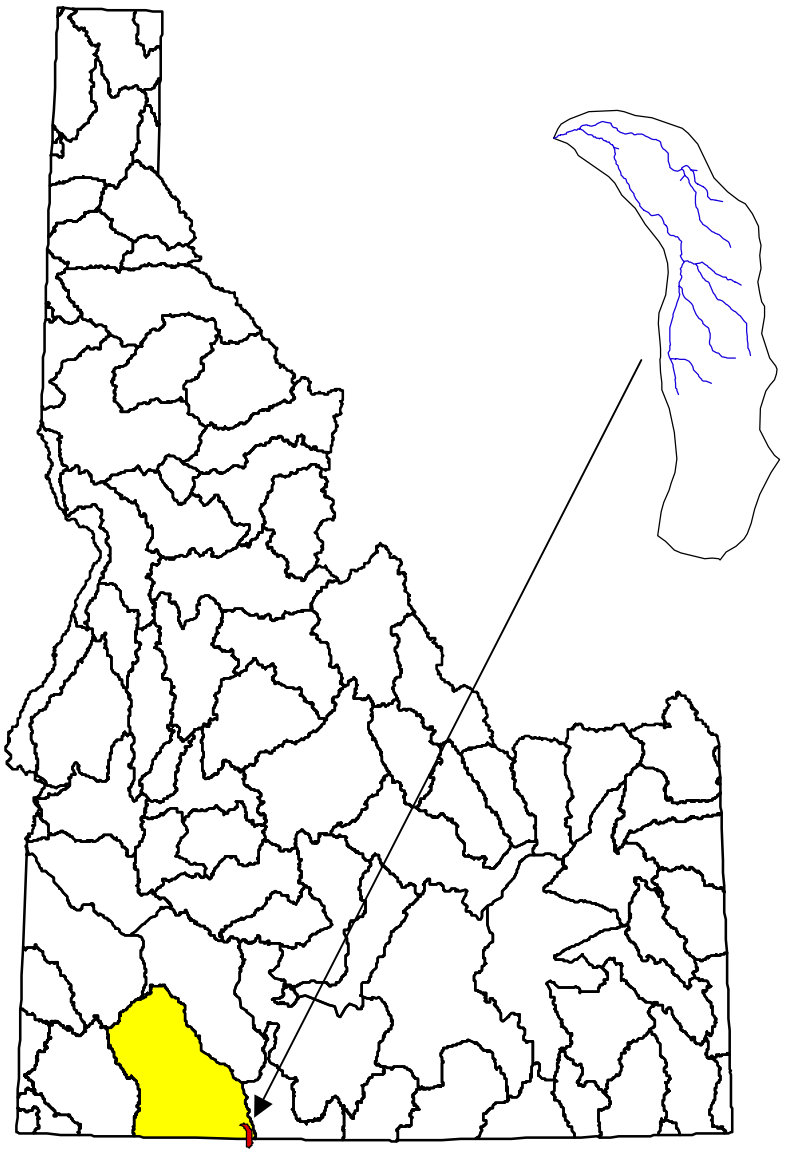

Figure 10-7. Deer Creek located in Bruneau HUC #17050102

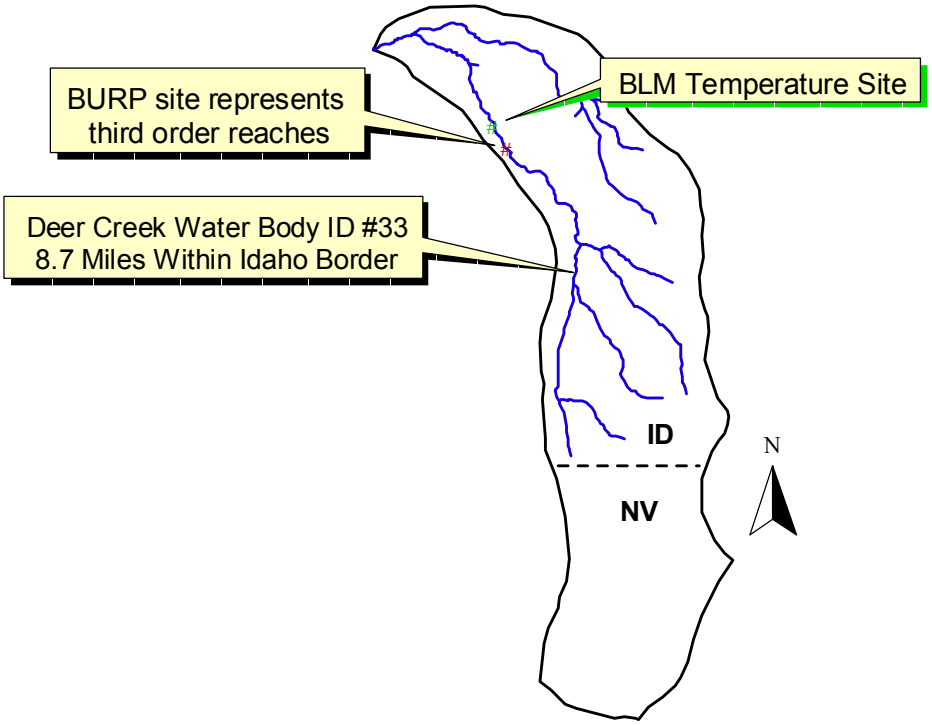

Figure 10-8. Deer Creek in 6th Field HUC #170501021003

10.2.2. Water Body Size Determination

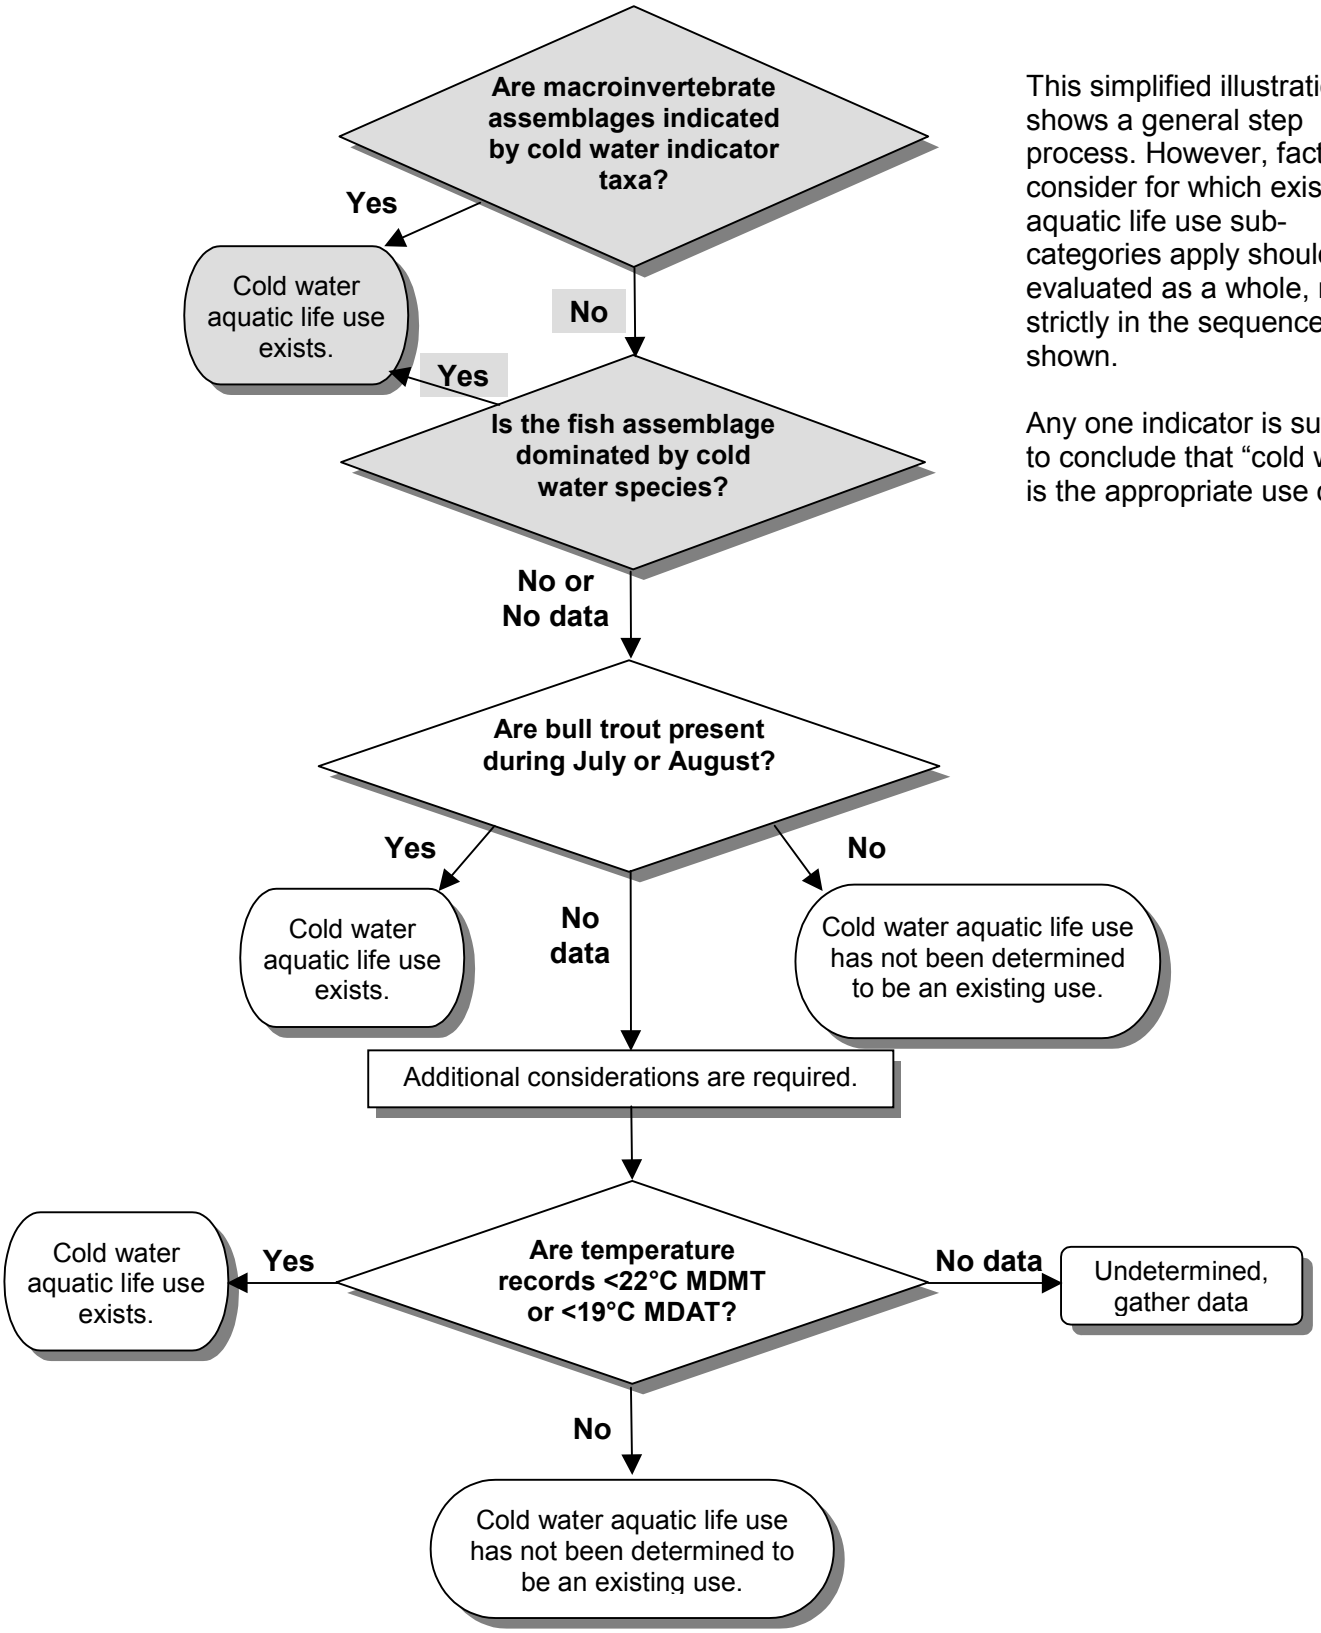
The average rating of water body size criteria is 1 and accordingly, Deer Creek is classified as a stream. Table 10-6 summarizes the results of the water body size determination.

Table 10-6. Summary of water body size criteria results for Deer Creek

Criteria	Value	Rating
Stream order	3.00	1
Average width at base flow (m)	2.70	1
Average depth at base flow (m)	0.18	1
	Average Rating	1

10.2.3. Identification of Beneficial Uses for Assessment

Deer Creek is an undesignated water body. The electrofishing sample was comprised entirely of rainbow trout, a cold water species. Consequently, the cold water aquatic life beneficial use was identified because the fish assemblage was dominated by cold water species (see Section 3 and Appendix C). Figure 10-10 illustrates this identification. Since the sample had juvenile salmonids measuring less than 100 mm, salmonid spawning was also identified as a beneficial use. Lastly, secondary contact recreation was selected since this stream is fairly small and has limited recreation.



This simplified illustration shows a general step process. However, factors to consider for which existing aquatic life use sub-categories apply should be evaluated as a whole, not strictly in the sequence shown.

Any one indicator is sufficient to conclude that "cold water" is the appropriate use class.

Figure 10-9. Identification of Beneficial Uses for Deer Creek

10.2.4. Evaluation of Existing and Readily Available Data

DEQ collected macroinvertebrate, fish, and habitat data at one BURP site in the lower section of the stream. BLM collected temperature data from June 4 – September 23, 1997, approximately one-quarter mile downstream from the BURP site. The macroinvertebrate, fish, and habitat data were collected using BURP protocols and consequently, are evaluated as TIER I and BURP compatible. The temperature data was collected using thermagraphs and also met Tier I criteria. Table 10-7 summarizes the evaluation of existing and readily available data.

Table 10-7. Summary of data evaluation for Deer Creek

Data Type (Source)	Tier	BURP compatible?	Associated with numeric criteria?	Analysis and conclusions reached?	Action
Macroinvertebrate (DEQ)	I	Yes	No	No	Calculate SMI score and assess according to Section 6.
Fish (DEQ)	I	Yes	No	No	Calculate SFI score and assess according to Section 6.
Habitat (DEQ)	I	Yes	No	No	Calculate SHI score and assess according to Section 6.
Temperature (BLM)	I	NA	Yes	No	Assess according to Section 5.

10.2.5. Criterion Exceedance Evaluation

Section 5 describes the policies for evaluating narrative and numeric criteria. DEQ interprets narrative criteria using biological data as applied in the ALUS process.

Temperature was the only data type associated with numeric criteria. DEQ uses guidance found in Section 5.2.1-4 to interpret temperature data for the cold water aquatic life and salmonid spawning. The assessor first determines if there is a temperature exemption due to air temperature extremes during the time of data collection (see Section 5.2.2.and Appendix E). There is no temperature exemption, so the assessor next determines if the temperature was measured during the critical time period for cold water aquatic life and salmonid spawning.

The temperature data was collected from June through September and therefore meets the critical time period requirement for cold water aquatic life (i.e., June 22 through September 21; see Section 5.2.1.). Next, the assessor identifies fish species collected during the BURP monitoring and uses Table 5-2 or Appendix F to ensure data were collected during the critical salmonid spawning time period. The critical spawning period for redband/rainbow trout is March 15 through July 15. DEQ evaluates the BLM temperature data within this time period to evaluate exceedances specific to salmonid spawning criteria (see Appendix D).

The next step is to calculate the percent of temperature exceedances for cold water aquatic life and salmonid spawning. If the percent of temperature exceedances is greater than 10, then DEQ determines a numeric criterion violation has occurred. Table 10-8 provides a summary of these numeric criteria results that will be incorporated in ALUS determinations described in Section 6.

Table 10-8. Summary of criteria exceedances and violations for Deer Creek

Beneficial Use	Criterion	% Exceedance	Violation
Cold Water Aquatic Life	19°C daily average	1%	No
	22°C daily maximum	22%	Yes
Salmonid Spawning (Spring)	9°C daily average	95%	Yes
	13°C daily maximum	73%	Yes

10.2.6. Aquatic Life Use Support Determination

10.2.6.1. ALUS Determination for Cold Water Aquatic Life

Table 10-9 summarizes the macroinvertebrate, fish and habitat index calculations for the available BURP compatible data. These index results then receive condition ratings for data integration purposes. In assigning these ratings, the assessor uses the following classifications: basins (Table 6-1, SMI), rangeland (Table 6-2 SFI), and Snake River Basin/High Desert (Table 6-3 SHI) classifications.

Table 10-9. Stream index scores and corresponding condition ratings for Deer Creek

Monitoring Station	SMI Score	SMI Condition Rating	SFI Score	SFI Condition Rating	SHI Score	SHI Condition Rating	Condition Rating Average
Site	35	NA	79	2	68	3	2.5

The assessor observes the particularly low SMI score relative to the SFI and SHI scores. In reviewing the macroinvertebrate data sheet, the assessor notes only 121 individuals were collected. DEQ attempts to collect a minimum of 500 individuals and does not calculate the SMI index if there are less than 150 individuals in the sample. This example

illustrates the benefit of using more than one assemblage to make an ALUS determination.

After noting the low macroinvertebrate sample size, the assessor then incorporates numeric criteria results. Although the average condition rating is 2.5, there are violations of the cold water aquatic life temperature numeric criteria (see Table 10-8) resulting in a not fully supporting determination. Figure 10-10 depicts this decision process.

10.2.6.2. ALUS Determination for Salmonid Spawning

As mentioned previously, DEQ evaluates salmonid spawning within the context of the ALUS determination and applicable numeric criteria. The preliminary ALUS determination indicated not fully supporting due to cold water aquatic life numeric criteria violations. Consequently, the salmonid spawning determination is not fully supporting. Salmonid spawning also would have been determined not fully supporting due to violations of specific salmonid spawning criteria. Figure 10-11 illustrates this decision process.

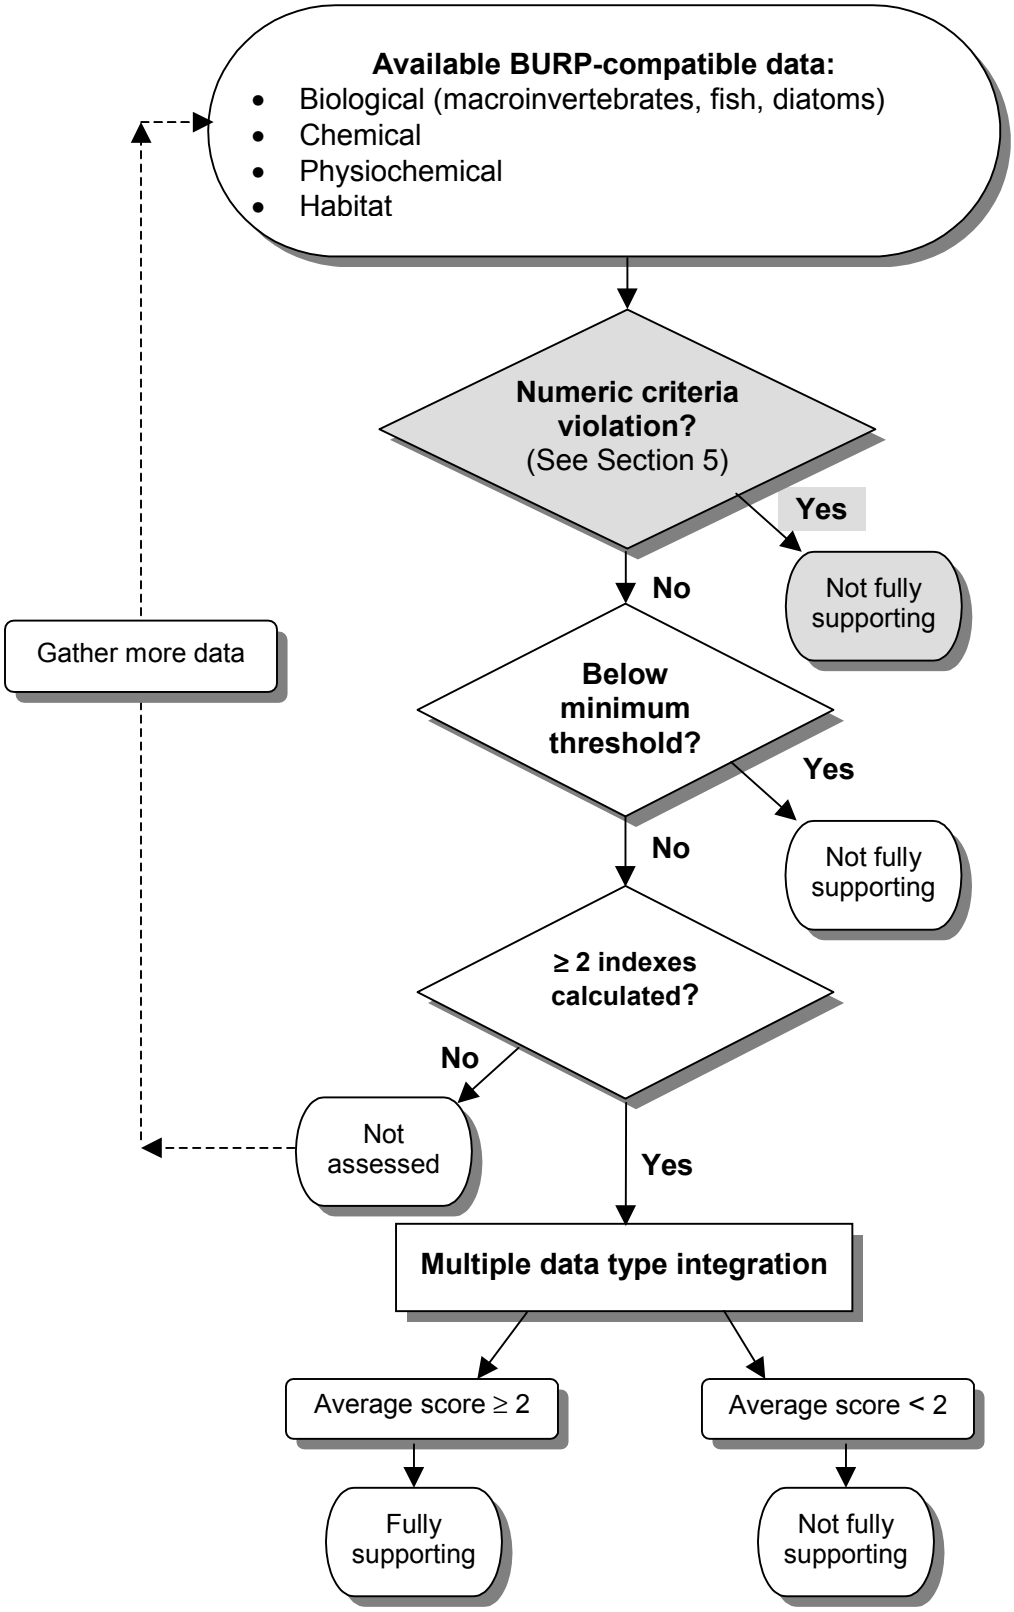


Figure 10-10. Stream cold water aquatic life use support determination for Deer Creek

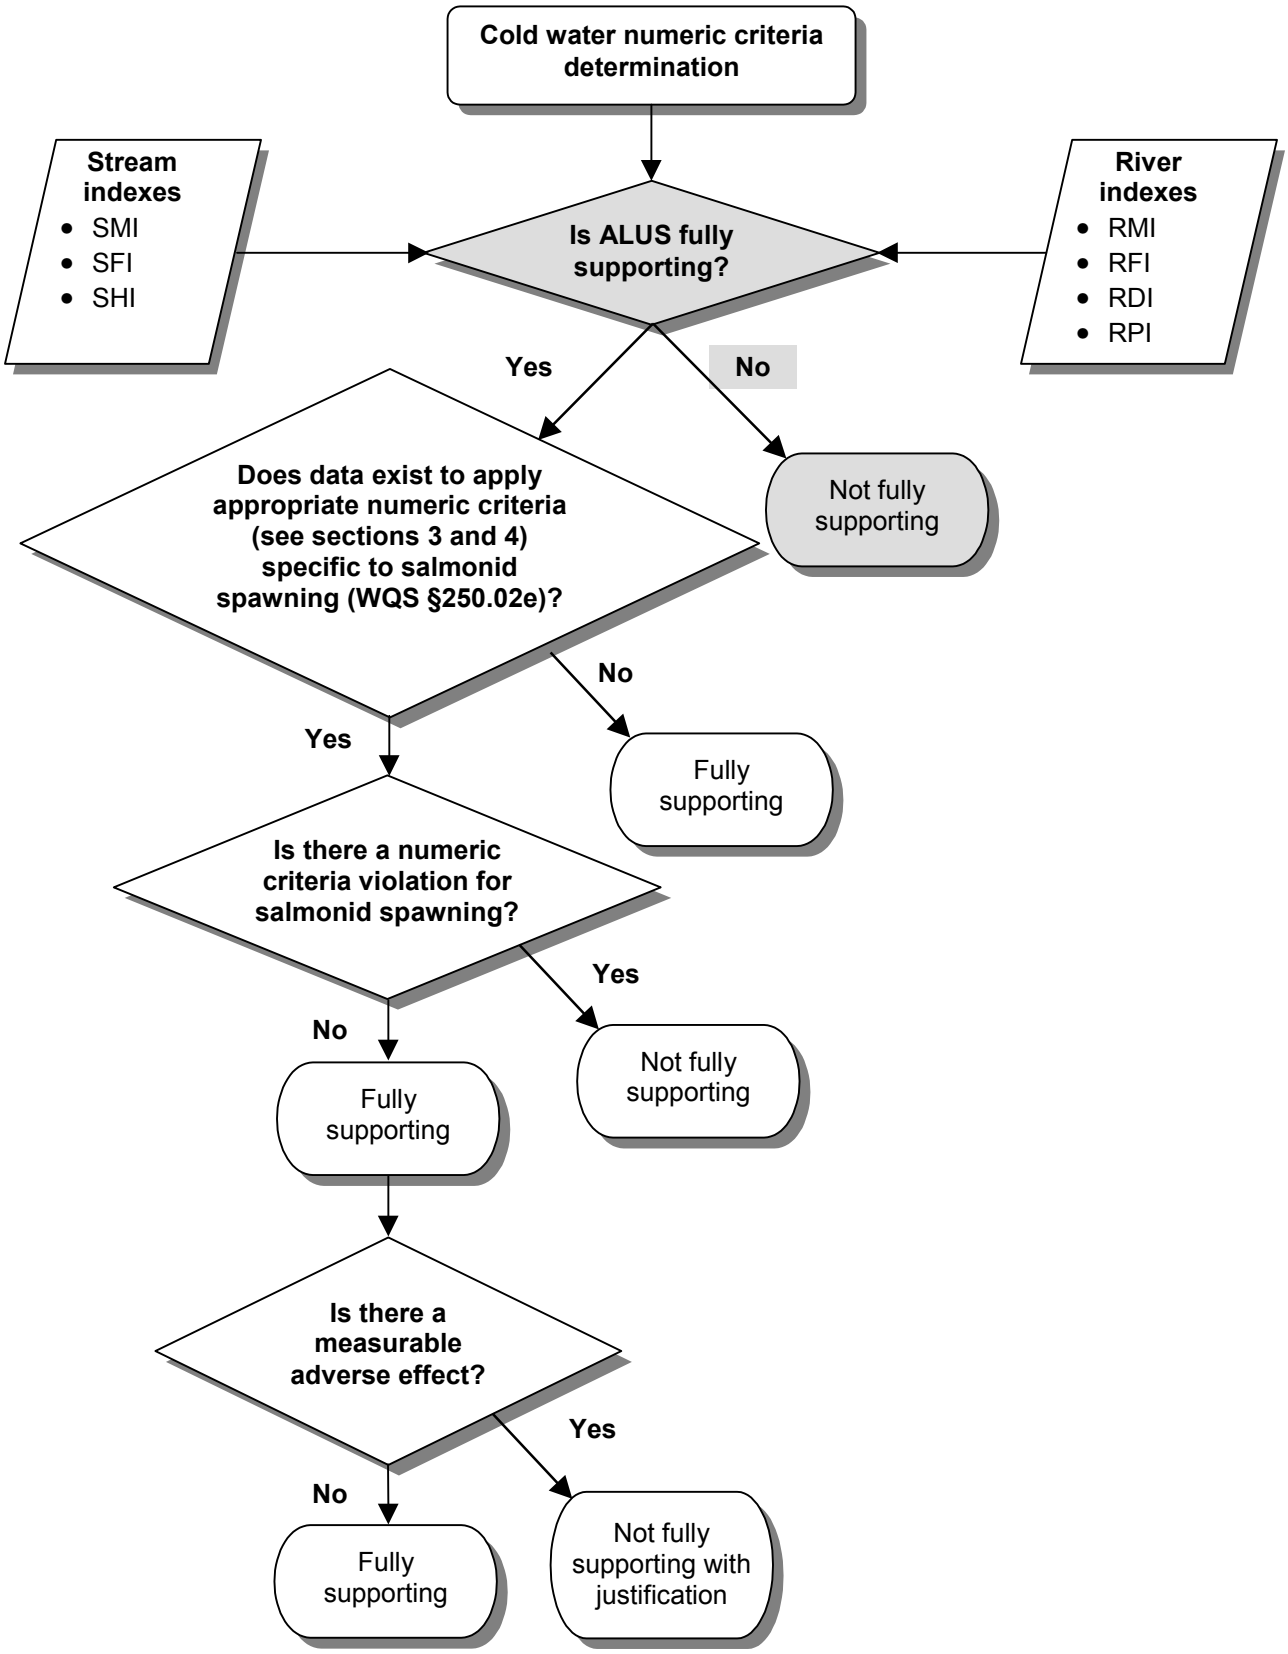

Figure 10-11. Stream salmonid spawning use support determination for Deer Creek

10.2.7. Contact Recreation Use Support Determination

For this example, there were no bacteria data available. As a result, the assessor applies the bacteria screening procedure (see Section 7.4.). This procedure entails using GIS procedures and local knowledge to determine if upstream land uses have the potential for increasing human pathogens. The assessor determined there was medium to high potential risk because moderate grazing occurs in the area. Therefore, contact recreation is unassessed until additional data are collected. Figure 10-12 depicts this decision process.

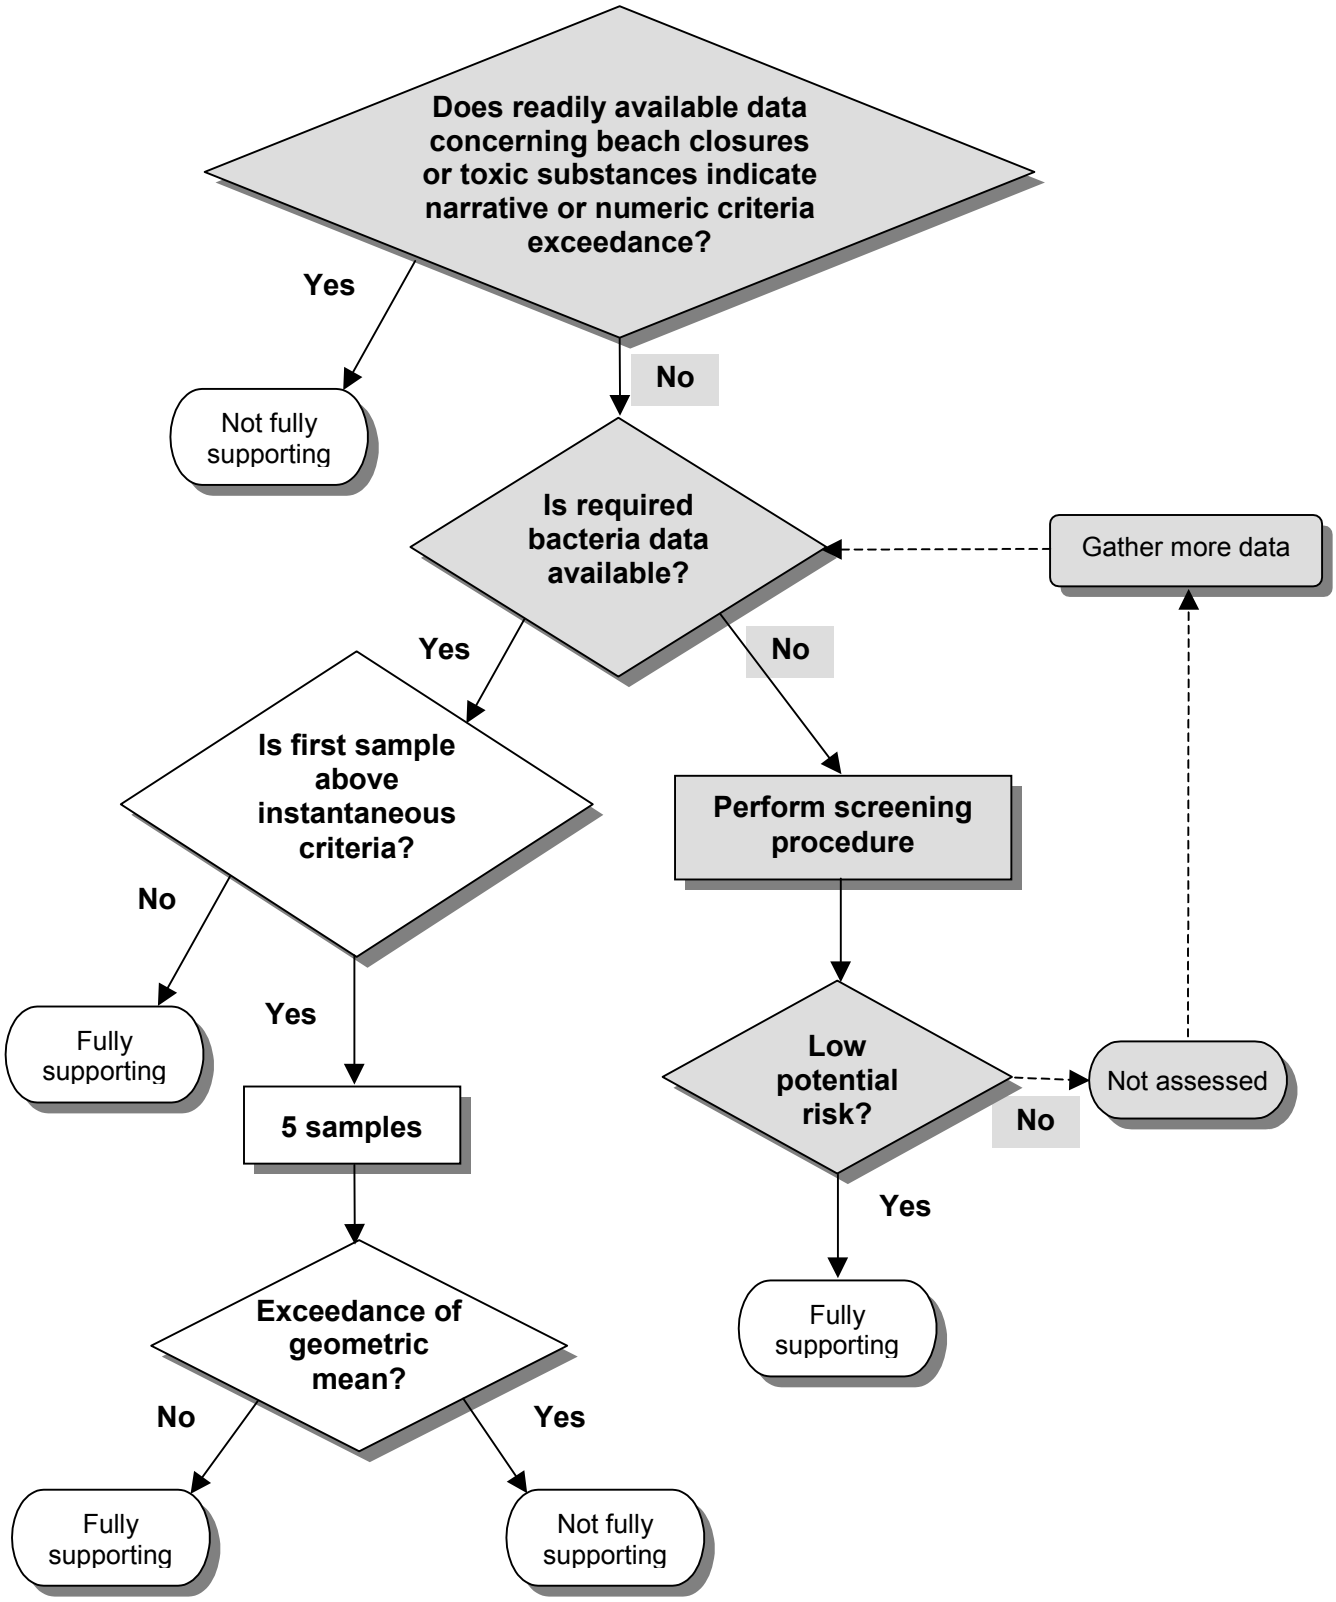

Figure 10-12. Contact recreation use support determination for Deer Creek

10.2.8. Summary of Beneficial Use Support Determinations for Deer Creek

DEQ had no evidence to the contrary of a fully supporting determination for water supply, wildlife habitat, and aesthetic beneficial uses (see Sections 8 through 9). Table 10-10 summarizes the entire Deer Creek assessment and indicates not fully supporting for aquatic life due to temperature criteria violations.

Table 10-10. Summary of beneficial use support determinations for Deer Creek

Beneficial Use	Support Determination	Basis for Determination
Aquatic Life	Not Fully Supporting	Index results indicate fully supporting; however, temperature violations of both cold water aquatic life and salmonid spawning criteria result in a not fully supporting determination.
Contact Recreation	Unassessed	No bacteria data and bacteria screening procedure.
Water Supply, Wildlife Habitat, and Aesthetics	Fully Supporting	No evidence to the contrary and policy.

Section 11. Public Appeals Process

There are several reasons why the public may wish to appeal a beneficial use support determination. First, DEQ may not have used all existing and readily available data in the assessment (see Section 4). Although DEQ attempts to request data from known sources, it is possible to miss data collected by all sources, particularly if those data were not submitted to DEQ for consideration. Also, the public may disagree with a DEQ interpretation of the data results and consequently, the use support determination. This might occur when the assessor diverges from the WBAG and provides a documented rationale for this difference. In this case, the public may not agree with the justification provided by the assessor.

The public may appeal or comment on a water body use support determination during the identified public comment period for that determination. DEQ holds public comment periods for scheduled 303(d) lists (required every two years according to the CWA) and individual subbasin assessments. The public may provide comment concerning use support determinations of specific water bodies at these times.

Individuals should contact the DEQ state office through a public record request (PRR), if they wish to review any appeals. In general, the DEQ state office manages all public appeals and comments associated with the 303(d) list. Appropriate regional offices handle public appeals and comments concerning particular subbasin assessments, and a copy of an appeal will be provided to the DEQ state office for reference only.

Appendix A. Empirically Derived Macroinvertebrate Cold Water Indicator List

Some factors are critical in determining species presence/absence and community structure (Sweeney 1984). One of the factors thought to be key in aquatic community structure is water temperature (Thieneman 1954). The relationship between macroinvertebrates and stream temperature is known for a limited number of taxa. Literature values are helpful but may not reflect the macroinvertebrate assemblages found in Idaho. In an attempt to determine the obligate cold water taxa found in Idaho streams DEQ analyzed the temperature data and macroinvertebrate communities of more than 1000 sampling locations. From this information DEQ was able to determine the probability of an individual taxa being present in any given temperature. Specifically, 137 of 289 common taxa exhibited a distinct temperature preference. Cold water obligates were determined by selecting the taxa that had less than a 10 percent probability of occurring in streams where the water temperature exceeded 19^{o}C. This resulted in 64 cold water obligate taxa. As an additional check the weighted mean of stream temperature and probability of occurrence was calculated. This calculation gave DEQ the preferred temperature of the taxa. The empirically derived obligate cold water taxa as well as the temperature preference of the taxa can be found in Table A-1.

Table A-1. Idaho Cold Water Taxa and Temperature DEQ Preferences

ORDER	Genus/Species	Temperature Preference

	Rhyacophila vofixa gr.	8.57
Tricladida		
	Polycelis coronata	9.76

Appendix B. Macroinvertebrate Taxa List – Temperature Tolerance

Table B-1 describes the fields used in the macroinvertebrate taxa list with corresponding temperature tolerances (see Table B-2). The temperature tolerance assignments were derived from literature searches and are continually updated. The entire macrinvertebrate taxa list is quite voluminous. For information about other macroinvertebrate attributes or to obtain the most recent taxa list, please contact DEQ Surface Water Program or visit the DEQ web site http://www2.state.id.us/index.htm and follow web links to surface water.

Table B-1. Field descriptions of macroinvertebrate taxa list – temperature tolerance

Field	Description
TAXON	Taxon number assigned by Idaho
TAXONNAME	Taxonomic identification
ORDER	Taxonomic order
FAMILY	Taxonomic family
TEMPTOL	Temperature tolerance derived from literature search. Eurythermal describes a wide range of temperature as opposed to stenothermal which is a narrow range of temperature.

Table B-2. Macroinvertebrate taxa list with corresponding temperature tolerances (sorted by taxon name)

TAXON	TAXONNAME	ORDER	FAMILY	TEMPTOL
993	Ablabesmyia sp.	Chironomidae (family)	Chironomidae	Eurythermal
459	Acamptocladius sp.	Chironomidae (family)	Chironomidae	Eurythermal: warm summer
453	Acari	Acari (subclass)		Eurythermal: warm summer
601	Acentrella insignificans	Ephemeroptera	Baetidae	Eurythermal: warm summer
640	Acentrella sp.	Ephemeroptera	Baetidae	Eurythermal: warm summer
781	Acentrella turbida	Ephemeroptera	Baetidae	Eurythermal: warm summer
702	Acentria sp.	Lepidoptera	Pyralidae	
1147	Acricotopus sp.	Chironomidae (family)	Chironomidae	

TAXON	TAXONNAME	ORDER	FAMILY	TEMPTOL
793	Aelosoma sp.	Aphanoneura (class)	Aelosomatidae	Eurythermal: warm summer
4	Aeschnidae	Odonata	Aeschnidae	
932	Aeshna sp.	Odonata	Aeschnidae	Eurythermal: warm summer
992	Agabinus sp.	Coleoptera	Dytiscidae	Eurythermal: warm summer
588	Agabus sp.	Coleoptera	Dytiscidae	Eurythermal: warm summer
171	Agapetus sp.	Trichoptera	Glossosomatidae	Eurythermal: warm summer
643	Agathon sp.	Diptera	Blephariceridae	Stenothermal: cold
181	Agraylea sp.	Trichoptera	Hydroptilidae	Eurythermal: cool summer
201	Allocosmoecus partitus	Trichoptera	Limnephilidae	Stenothermal: cold
795	Allognosta sp.			
875	Allomyia sp.	Trichoptera	Apataniidae	Stenothermal: cold
131	Alloperla sp.	Plecoptera	Chloroperlidae	Eurythermal: warm summer
819	Ambiguelmis sp.			
597	Ambrysus sp.	Hemiptera	Naucoridae	Eurythermal: warm summer
962	Ameletus celer	Ephemeroptera	Ameletidae	Eurythermal: cool summer
634	Ameletus connectus	Ephemeroptera	Ameletidae	Eurythermal: cool summer
579	Ameletus cooki	Ephemeroptera	Ameletidae	Eurythermal: cool summer
693	Ameletus similor	Ephemeroptera	Ameletidae	Eurythermal: cool summer
13	Ameletus sp.	Ephemeroptera	Ameletidae	Eurythermal: cool summer
711	Ameletus sparsatus	Ephemeroptera	Ameletidae	Eurythermal: cool summer
587	Ameletus validus	Ephemeroptera	Ameletidae	Eurythermal: cool summer
14	Ameletus velox	Ephemeroptera	Ameletidae	Eurythermal: cool summer
961	Ametor sp.	Coleoptera	Hydrophilidae	Eurythermal: cool summer
718	Ametropus sp.	Ephemeroptera	Ametropodidae	Eurythermal: cool summer
501	Amiocentrus aspilus	Trichoptera	Brachycentridae	Eurythermal: warm summer
232	Amiocentrus sp.	Trichoptera	Brachycentridae	Eurythermal: warm summer

Appendix C. Fish Taxa List

Table C-1 is a list of fish taxa and attributes used in the water body assessment guidance. The principal source was Zaroban et al. (1999). Some exceptions are mottled sculpin (see Stream Fish Index report), genus and family level classifications, and for some additional introduced species.

Table C-1. Fish taxa

Table notes:
(1) Sensitivity: S – senstive; I – intermediate; T – tolerant. Sensitive species are those that are typically intolerant of siltation, turbidity, increased water temperature, and lowered dissolved oxygen and tend to be replaced by intermediate or tolerant species. Tolerant species are considered those that tend increase in abundance with human disturbances particularly in relation to increased siltation, turbidity, and water temperature and decreases in dissolved oxygen (Zaroban et al. 1999).
(2) Temperature classifications: CLD – Cold water; COL – cool water; WRM – warm water

Appendix D. Temperature Frequency of Exceedance Calculation Procedure

Memorandum

To: DEQ Water Quality Staff

From: Don Essig, Temperature Issues Coordinator, and
Chris Mebane, Water Quality Standards Program manager

Date: January 3, 2002

Re: Temperature Frequency of Exceedance Calculation Procedure, Revised

This memo builds on and strives to clarify application of the policy on allowable frequency of exceedance contained in WBAG II. It represents DEQ's further interpretation of Idaho's water quality criteria for temperature. This revision of the original Oct. 22nd, 2001 memo better addresses cases in which greater than 10% exceedance are apparent with less than a complete data record.

The 10% criteria exceedance policy is for 303(d) listing and de-listing decisions. It is still necessary to target the current water quality criteria in crafting a TMDL. However if your frequency of exceedance of the temperature criteria is less than 10%, and there is no other evidence of thermal impairment, then it is possible to move for de-listing rather than proceed with a temperature TMDL. If you proceed with a temperature TMDL, then during implementation of the TMDL the water will be reassessed. In that reassessment the goal for temperature would be considered met if criteria exceedances fall below 10% for a 90 percentile air T year (per our Air T exemption).

Frequencies of temperature exceedance must be calculated on the metric of interest (e.g., the frequency of daily maximum stream temperature exceeding daily maximum criteria). Except for single daily maximum criteria, this requires data processing of the raw temperature record before counting exceedances. What follows is more detail on calculation of a criteria exceedance frequency for water temperature.

Time periods of interest

For ***cold water aquatic life*** the summer period of June 21st through September 21st shall be considered the period of interest on which to gage frequency of exceedance. This 93 day period acknowledges the natural seasonal progression of water temperature in which peak water temperature typically occur between

July 15th and August 15th, with progressively cooler temperature generally to either side.

For ***salmonid spawning*** the time period of interest is the entire spawning and incubation period ***at a given site***, but not less than 45 days. Forty five days is set as a minimum spawning period as this allows 2 weeks for spawning and an additional month for egg incubation. The frequency of exceedance of salmonid spawning criteria should be based on the entire spawning and incubation period of the site in question. Note that the entire spawning period at a site, even when greater than 45 days, will usually be shorter than the broad periods that were formerly in Idaho's water quality standards. Those broad periods, often still used as rules of thumb, were intended to encompass spawning times statewide and from valley to mountain, not what would occur at any particular site.

Critical time period

In absence of data to the contrary, critical periods for water temperature are defined as follows. For ***cold water aquatic life*** the critical time period is from July 15th through August 15th, the time period when most streams reach there highest temperature of the year. Spawning often occurs when water temperatures are in a spring or fall transition. Therefore, for ***salmonid spawning*** the critical time period is the 22 days at the warmer end of the spawning period. For spring spawners this will be at the chronological end of the period, while for fall spawners this will be at the chronological beginning of the period.

Complete data records

In order to calculate and evaluate a percent exceedance for temperature an adequate data record is needed. The best situation is to have a complete data record for the entire period of interest as defined above and that should be the goal in any future monitoring effort. However it is acknowledged that this is not always the case, even when planned, and furthermore much historical data will not have been collected with this policy in place. Therefore the following allowances are made for evaluating partial data records.

Partial data records

For purposes of evaluating a frequency of exceedance partial data records that do not include the critical time periods are inadequate for estimating a frequency less than 10% and therefore can not be used to determine compliance with Idaho's temperature criteria.

On the other hand, partial data records that do not include the critical time periods may be sufficient to estimate a frequency of exceedance that is at least 10% and thus a violation of criteria. This occurs when the observed number of days over criteria in the partial record is greater than the number of days necessary to reach 10% exceedance for the entire period of interest. Take ***salmonid spawning*** for example, if a partial data record includes 41 days of a 90 day spawning period, and 15 of those days are over criteria then the frequency of exceedance is at least 15/90 = 17%, even if it were assumed the 49 days without data met criteria. For ***cold water aquatic life*** a frequency of

exceedance greater than 10% is documented with ten days of exceedance, even if those ten days are the only data available (10/93 = 11%). Data records less than 10 days for ***cold water aquatic life*** or less than 10% of the applicable spawning period are inadequate to show a frequency of exceedance that is at least 10% and are therefore inadequate to determine violation of Idaho's temperature criteria.

If the partial data record includes the critical time period it may be possible to infer the frequency of exceedance is not more than 10%. For ***cold water aquatic life***, if the partial data record includes the critical period from July 15 thru August 15th inclusive and the frequency of exceedance is less than 10%, then it can be assumed the frequency of exceedance for the entire summer period of interest is less than 10%. Similarly, if the data record during ***salmonid spawning*** includes the warmest 22 days of the spawning period (end or beginning of the time period depending on whether spawning extends into spring or fall) and the frequency of exceedance is less than 10%, then it can be assumed that the frequency of exceedance is less than 10% for the entire spawning period.

If calculated frequency of exceedance is greater than 10% for a partial data record it may still be possible to infer a frequency of exceedance as if data for the entire period of interest had been collected. To do so one must examine the data record and consider seasonal trends in temperature.

If the last (or first) seven consecutive days at the cool end of the record show no exceedances of criteria, then it may be assumed the entire following (preceding) unmonitored portion of the time period of interest is also without exceedances. In which case an inferred frequency of exceedance may be calculated using the entire period of interest as the denominator. For example, lets say the period of interest is a spawning period which begins May 1st and ends June 30th. The available data record however begins June 1st and shows 5 exceedances of a 13°C daily maximum criterion. The calculated frequency of exceedance is 5/30 = 17%. Further examination of the data record reveals that all 5 exceedances occurred after June 15th with no exceedances in the first 7 days of June, at the cooler beginning of the record. It can therefore be assumed that had data been obtained for May it would also show no exceedances of the criterion. The inferred frequency of exceedance for the entire spawning period would be 5/61 = 8%, no violation of standards.

Appendix E. Regional Application of the Idaho Water Quality Standards Temperature Exemption

E.1. Background

Ambient air temperature is one of the principal factors correlated with stream temperatures. It is also one factor that has been regularly monitored at a number of National Weather Service reporting stations for many years, allowing a statistical analysis of frequency of exceedance. When air temperatures are unusually hot, stream temperatures rise and may exceed fixed criteria for no other reason than the weather. For this reason the Idaho Water Quality Standards and Wastewater Treatment Requirements (Water Quality Standards) exempts the numeric temperature criteria when the air temperature exceeds the 90th percentile of the annual maximum weekly maximum temperatures (MWMT) as determined from the historical record of a nearby weather station (IDAPA 58.01.02.080.04). There is only one MWMT per year, and only 1 year in 10, on average, will see the MWMT greater than the 90th percentile value. The exemption is narrow by design and should take effect only rarely, on the hottest days of a warm summer and likely not at all in most years.

E.2. Explanation

Although not the only factor affecting day to day changes in water temperature, we do expect water temperature to be unusually high when the weather is unusually hot. When the air temperature is unusually hot at one reporting locale, the air temperature is likely to be unusually high throughout the region. Since weather is a regional phenomenon, the temperature exemption is applied to regions of similar climate.

To that end, the maximum air temperature records for the past thirty years (1970-1999) were obtained for stations in the 10 climate divisions in Idaho set by the National Climatic Data Center (NCDC). The climate divisions established by NCDC are standardized regions within each state that designate areas of similar climate regimes (NCDC 2000a). The stations were chosen because they are both representative of their climate divisions and compared to other stations in their climate division, have a longer record of temperatures. Due to the size of climate division 4, records were obtained for three stations, one each in northern, southwestern, and central Idaho in order to provide a closer regional comparison. Table E-1 summarizes the locations of the stations used in this report and Figure E-1 identifies NCDC divisions.

Table E-1. Weather Stations Attributes

Climate Division	Coop ID	Station Name	County	Latitude/Longitude	Elevation (m)
1	101956	Sandpoint	Bonner	48°18' N, 116°33' W	640.1
2	106152	Moscow	Latah	46°44' N, 116°58' W	810.8

Figure E-1. National Climatic Data Center (NCDC) Climate Divisions

E.3. Process / Results

To identify the air temperature thresholds for the exemption, the 90 th percentile of the maximum weekly maximum temperature of the air for the above weather stations was calculated. First, a 7-day rolling average of the record was calculated for the 30-year period used to define climatic norms. Next, the highest value for the 7-day rolling averages, or the MWMT, was selected within each calendar year. For some stations (i.e., Kellogg, Stanley, Hollister, and Driggs), an accurate MWMT could not be determined in select years due to missing records in the summer months.

For each station, the 90th percentile of the annual series of MWMT was calculated. These are given in Table E-2 in both Fahrenheit and centigrade.

Table E-2 is provided for convenience and is not intended to preclude others from determining a 90th percentile air temperature threshold for a weather reporting station nearer their stream of interest, or for the most recent 30-year period.

Table E-2. 90th Percentile of Maximum Weekly Maximum Air Temperatures

Climate Division	Station Name	90th % MWMT (°F)	90th % MWMT (°C)
1	Sandpoint	92.60	33.67
2	Moscow	96.04	35.58
3	Lewiston	102.33	39.07
4	Kellogg	98.71	37.06
4	McCall	91.00	32.78
4	Stanley	87.80	31.00
5	Boise	101.30	38.50
6	Hollister	93.66	34.26
7	Twin Falls	94.44	34.69
8	Salmon	97.40	36.33
9	Pocatello	97.04	36.13
10	Driggs	88.60	31.44

Note: The Idaho Department of Environmental Quality has a spreadsheet used to calculate these values

E.4. Conclusion

The above calculations provide a guideline to determine the criteria for temperature exemptions within each climate division (see Figure D-1). The Water Quality Standards call for the nearest weather station to be used. The NCDC climate divisions, however, are representative of regional climate regimes and thus provide a general measure to show how the Water Quality Standards apply. For example, for a stream within climate division 8, the air temperature would need to exceed 97.4°F (36.3°C) in Salmon for the Water Quality

Standards' temperature exemption to take effect. For the three stations in climate division 4 used, the Water Quality Standards state that the nearest weather reporting station should be used.

Appendix F. Time Periods for Salmonid Spawning

F.1. Time Periods for Salmonid Spawning

Section 5.2.4 summarizes general issues relating to the application of salmonid spawning and incubation for trout, salmon, and whitefish occurring in Idaho. This appendix describes some additional considerations and lists some reported spawning times for specific water bodies for Chinook salmon, *Oncorhynchus mykiss* (i.e., rainbow/ redband/ steelhead trout), and cutthroat trout. These species were selected for the bibliography because they are widespread native salmonids. Spawning times for bull trout were not considered since these are prescribed by regulation (September – October); therefore, when bull trout actually spawn is not relevant for the question of what time periods spawning criteria apply (WQS § 250.02.f). Spawning periods for mountain whitefish were not considered in detail because they spawn in late-fall and winter and maximum temperature criteria are not much of an issue at those times.

The salmonid spawning and incubation time periods listed in Table 5-2 and F-1 below were intended to reflect typical, core-time periods for spawning and incubation. The table was not intended to capture the extremes of variations in life histories reported for species.

Table F-1. Common core-periods for spawning and egg incubation for several native and introduced salmonid species in Idaho

Fish Species	(Annually) Time Period	Fish Species	(Annually) Time Period
Chinook salmon (spring/summer)	Aug 15 - June 1	Bull trout	Sept 1 - Apr 1
Chinook salmon (fall)	Oct 1 - Apr 15	Kokanee salmon	Sep 1 - May 1
Sockeye salmon	Oct 1 - June 1	Mountain whitefish	Oct 15 - Mar 15
Steelhead trout	Apr 1 - July 15	Brown trout	Oct 1 - Apr 1
Redband/rainbow trout	Mar 15 - July 15	Brook trout	Oct 1 - June 1
Cutthroat trout	Apr 1 – Jul 1		

Table notes: Principle sources consulted were Scott and Crossman (1998), Wydoski and Whitney (1979), Simpson and Wallace (1982), and for bull trout WQS 250.02.f. Days of the month ("1", "15") indicate early or mid-month; no higher precision is intended.

Unfortunately, selecting time periods to apply temperature criteria for salmonid spawning is somewhat circular. For example, temperature criteria suitable for salmonid spawning apply during time periods when salmonids are spawning (WQS § 250.02.e). Salmonids are cued to spawn during times when

temperatures become suitable. For example, for spring spawning species such as cutthroat trout and rainbow/redband/steelhead trout, spawning is initiated when temperatures rise to about 6 – 9°C (Benke 1992). Stream temperatures rise and spawning occurs as the weather warms in the spring. Thus, the time periods for applying temperature criteria suitable for spawning are determined by when temperatures are suitable for spawning. This tautology makes meaningful application of criteria difficult. The recommended approach for applying these criteria for assessment of many streams (e.g., 303(d) listing) is to compare observed temperatures over the available estimates of core time periods of spawning and incubation for the area of interest. If salmonid spawning numeric criteria are exceeded (9°C daily average or 13°C daily maximum) during these core-time periods, then violations of salmonid spawning temperature criteria should be determined in accordance with the criterion exceedance policy. For more focused evaluations (e.g., TMDL problem assessments or subbasin assessments), a more meaningful approach would additionally consider probable causes of the exceedance. Water quality standards are generally interpreted such that waters are not to vary from specified characteristics due to human activities. Thus, for focused evaluations, the assessor should consider if human activities within the watershed can be linked to increases in stream temperature. If so, criteria are violated; if not, temperature criteria are not violated. The level of analysis needed to distinguish natural from human-caused thermal sources is generally beyond the scope for broadscale evaluations (e.g., 303(d) water quality listing). Exceptions are likely limited to conditions when the assessor can readily determine that upstream of the measurement point, the watershed is completely free from roads or other mechanized disturbances in the riparian area of influence. Otherwise, more focused evaluations than are practical during the statewide 303(d) compilations are needed.

An additional consideration in applying salmonid spawning criteria is whether the time periods for applying spawning criteria would logically conflict with other life history requirements. For example, Harig and Fausch (in press) investigated minimum summer temperatures needed for translocated cutthroat trout to persist. Cutthroat trout spawn during the spring and are stimulated by rising temperatures, but cold water temperatures can delay spawning into late summer and prolong egg incubation, resulting in low embryo survival or increased time to fry emergence. Late-hatching fry may be unable to acclimate to a rapid decrease in water temperature or may starve during winter, so survival may depend on their ability to grow large enough to withstand metabolic deficits. Harig and Fausch (in press) found that in streams that support no or low numbers of cutthroat trout, cold temperatures (lesser than or equal to 7.8°C mean daily temperature for July) likely prevent successful reproduction and recruitment during most years. In streams ranked as supporting high numbers of cutthroat trout, summer water temperatures are probably warm enough (10.0°C mean July temperature) to allow successful reproduction and growth (Harig et al. 2000; Harig and Fausch, in press). Streams with daily maximum temperatures less than 9°C in July (spawning criteria) cannot have mean July temperatures of 10°C. In other words, temperatures that might be optimal for one life stage (less than 9°C for spawning and egg incubation), if maintained too long would reduce growth and juvenile survival. Therefore, overly broad application of spawning and egg incubation criteria could be counterproductive, rather than being necessarily “conservative” or “protective.”

Similarly, Thurow and King (1994) reported that cutthroat trout spawning *began* when mean daily temperatures rose above 10°C, and Magee et al. (1996) reported peak spawning of cutthroat trout occurred at mean daily temperatures of 8°C. These temperatures are near or above the less than 9°C spawning criteria, which indicates the criteria may be too low. Currently, these situations would be addressed by natural background provisions of the water quality standards. These provisions are that when natural background conditions exceed any numeric water quality criteria, criteria shall not apply; instead, pollutant levels shall not exceed the natural background conditions.

Hatching, the end of the incubation periods, can be estimated from reported fry emergence times. For criteria application, this may only be of practical interest for rainbow and cutthroat trout, the spring spawning species for which the egg incubation times extends into the summer heat. Rainbow trout eggs usually hatch 4-7 weeks after spawning, and alevins stay in the gravel for an additional 4-7 days. Cutthroat trout eggs usually hatch 6-7 weeks after spawning and alevins remain in the gravel another 1-2 weeks (Scott and Crossman 1998). These times, plus one to two weeks of spawning activity, result in minimum spawning and incubation periods on the order of 40-60 days.

Table F-2. Time of Spawning of Chinook salmon
Listed in order by run type, basin, and stream. "Basin" is used in generic sense; rather than a specific hydrologic or administrative definition.

Appendix H. Stream Aquatic Life Use Support Determination: Summaries of Metrics Used in Indexes

The stream ecological assessment framework integrates three multimetric indexes in the aquatic life use support determination. These indexes include the Stream Macroinvertebrate Index, Stream Fish Index, and Stream Habitat Index. Details describing the development of these indexes are found in *Idaho Stream Ecological Assessment Framework: An Integrated Approach* (Grafe 2002b). The following summaries describe the metrics and classification approaches used in the indexes.

H.1. Stream Macroinvertebrate Index

DEQ contracted Tetra Tech, Inc., to develop the Stream Macroinvertebrate Index (SMI). Benthic macroinvertebrates are aquatic insects found in bottom substrate. There are several reasons why macroinvertebrates are used as biological indicators of water quality. Macroinvertebrates:

- Indicate localized conditions because they are relatively sedentary.
- Integrate short-term environmental impacts due to their short life cycles.
- Allow experienced biologists to rapidly and easily examine water quality conditions.
- Comprise species possessing a wide range of trophic levels and pollution tolerances.
- Provide a primary food source for fish.
- Are relatively easy and economical to sample.
- Are abundant and diverse in most Idaho streams.

The details of the index development and supporting analysis may be found Jessup and Gerritsen (2000). In summary, Tetra Tech used sites identified as least impacted and as stressed to develop the SMI. Jessup and Gerritsen (2000) distinguished three classes, or bioregions, using two primary techniques: ordination and metric distribution comparisons. These bioregions, which are groupings of ecoregions, were Northern Mountains, Central and Southern Mountains, and Basins. Table H-1 identifies the ecoregions that are included in

these bioregions. The Northern Rockies ecoregion was divided into two bioregions: northern Northern Mountains and southern Northern Mountains. Preliminary analysis indicated that the Northern Rockies ecoregion contained biological characteristics that differed between the northern and southern portions. The ecoregion was therefore divided between the Clearwater River drainage to the north (northern Northern Rockies ecoregion) and the Salmon River drainage to the south (southern Northern Rockies ecoregion).

Table H-1. SMI Bioregion Classification

Northern Mountains	Central and Southern Mountains	Basins
Northern Northern Rockies	Southern Northern Rockies	Snake River Basin
	Blue Mountains	Northern Basin and Range
	Middle Rockies	Columbia Plateau
	Wasatch and Uinta Mountains	Wyoming Basin

Jessup and Gerritsen (2000) identified nine significant macroinvertebrate metrics to characterize water quality conditions. These SMI metrics include assemblage attributes such as richness, composition, pollution tolerance, diversity, feeding group, and habit. Table H-2 summarizes the metrics along with predicted responses to increasing perturbation. Jessup and Gerritsen (2000) provide descriptive formulas on how to calculate these metrics.

Table H-2. SMI Macroinvertebrate Metrics (Jessup and Gerritsen 2000)

Metric Categories	Metric	Definition	Predicted response to increasing perturbation
Richness	Total taxa	Number of distinct taxa in the macroinvertebrate assemblage	Decrease
	Ephemeroptera taxa	Number of mayfly taxa	Decrease
	Plecoptera taxa	Number of stonefly taxa	Decrease
	Trichoptera taxa	Number of caddisfly taxa	Decrease
Composition	Percent Plecoptera	Percent of sample that is stonefly nymphs	Decrease
Pollution tolerance	Hilsenhoff Biotic Index	Abundance-weighted average tolerance of organisms to pollution (Hilsenhoff 1987)	Increase
Diversity	Percent five dominant taxa	Percent of sample in the most abundant five taxa	Increase

Metric Categories	Metric	Definition	Predicted response to increasing perturbation
Feeding group	Scraper taxa	Number of taxa that scrape periphyton from substrates	Decrease
Habit	Clinger taxa	Number of taxa that have fixed retreats or adaptations for attachment to surfaces in flowing water	Decrease

H.2. Stream Fish Index

The Stream Fish Index (SFI) is a bioassessment tool that directly measures the achievement of the Clean Water Act "fishable" goal. Details of the development of this index along with supporting analysis may be found in Mebane (2002a).

Mebane (2002a) used sites identified as least impacted and as stressed to develop the SFI. He developed two site classes (bioregions) - montane-forested and desert basin-rangeland - after extensive literature review. Table H-3 identifies the general ecoregions included in these bioregion classifications.

Table H-3. Site Classification Based on Grouping of Ecoregions

Montane – Forested	Desert Basin – Rangeland
Northern Rockies	Snake River Basin/ High Desert
Middle Rockies	Northern Basin and Range
Blue Mountains	Columbia Basin
Wasatch-Uinta Mountains	Wyoming Basin

Mebane (2002a) identified two different sets of metrics to characterize water quality conditions for forested and rangeland classes. For rangeland sites, six metrics were identified comprising assemblage attributes such as richness, composition, indicator, abundance, and condition (Table H-4). The forest metrics also included richness, composition, indicator, and abundance characteristics, as well as reproductive function attributes. It should be noted that number of sculpin age classes is not included if the sample is comprised entirely of salmonids. Both classifications also incorporate amphibian indicators as a secondary metric. Table H-5 summarizes the forest metrics along with predicted responses to increasing perturbation.

Table H-4. SFI Metrics Used in Rangeland Classification (modified from Mebane 2000a)

Metric Categories	Metric	Definition	Predicted response to increasing perturbation
Richness and composition	% cold water individuals	Percent of individuals found in cold water streams. Includes introduced trout species.	Decrease
	Jaccard's community similarity coefficient	The degree of similarity in species composition between reference stations and the test site. Used eight most frequently occurring species at reference streams to define the assemblage.	Decrease
Indicator	% omnivores and herbivores	Percent of fish species that take significant quantities of plant and animal (including detritus) materials.	Increase
	% cyprinids as longnose dace	Percent of minnow species which are longnose dace. Of the native minnows, these may diminish with sedimentation, loss of riffle habitats, and diminished stream flows.	Decrease
Condition	% of fish with certain abnormalities	Percent of fish with external deformities, eroded fins, lesions, or tumors in response to exposure to contaminated sediments or other exposure routes.	Increase
Abundance	Catch per unit effort	Number of cold water individuals per minute of single-pass electrofishing.	Decrease

Table H-5. SFI Metrics Used in Forested Classification (modified from Mebane 2000a)

Metric Categories	Metric	Definition	Predicted response to increasing perturbation
Richness and composition	Number of cold water native species	Number of native fish species typically found in cold water streams. Excludes introduced or tolerant native fish species.	Decrease
	% cold water individuals	Percent of individuals found in cold water streams. Includes introduced trout species.	Decrease
	% sensitive native individuals	Percent of native individuals sensitive to perturbations such as increased turbidity, sediment, and warmer temperatures.	Decrease
Reproductive function	Number of sculpin age classes[1]	Number of sculpin age classes (use measured size classes to infer) reflects the availability of unembedded cobble substrate required for cavity nesters and juvenile refuge.	Decrease
	Number of salmonid age classes	Number of salmonid age classes reflects suitability and stability of conditions for salmonid spawning, juvenile rearing, and adult salmonids.	Decrease
Abundance	Catch per unit effort, CPUE	Number of cold water individuals per minute of single-pass electrofishing.	Decrease

[1] Number of sculpin age classes is not included if the sample is comprised solely of salmonids.

H.3. Stream Habitat Index

DEQ contracted Statistical Design and Rhithron Biological Associates to develop the Stream Habitat Index (SHI). The details of the index development and supporting analysis may be found in Fore and Bollman (2000).

Fore and Bollman (2000) determined that ecoregion groupings provided the most useful classification approach for the SHI. These groupings are identified in Table H-6.

Table H-6. SHI Classification Based on Ecoregions

Ecoregions
Northern/Middle Rockies
Snake River Basin/High Desert
Northern Basin and Range

Fore and Bollman (2000) used land use data to evaluate human disturbance gradients in the Snake River Basin and Northern Basin and Range ecoregions. In the Northern/Middle Rockies ecoregion, it is more difficult to develop such a disturbance gradient using available land use data so DEQ professional biologists identified least impacted and stressed sites based on observations of human disturbance at the site and in the watershed. Fore and Bollman (2000) also tested habitat measures with biological data (fish and macroinvertebrates). Ultimately, they identified 10 habitat measures (metrics) that signaled water quality conditions. Five of these metrics are quantitatively measured while the other five are field rated using eye estimates (Table H-7).

Table H-7. SHI Metrics (Fore and Bollman 2000)

Metric Categories	Metric	Field rated or measured	Predicted response to increasing perturbation
Epifaunal substrate/ available cover	Instream cover	Rated	Decrease
	Large organic debris	Measured	Decrease
Embeddedness/ heterogeneity of substrate composition	Percent fines <2mm in wetted width	Measured	Increase
	Embeddedness	Measured	Increase
	Wolman size classes (number)	Measured	Decrease
Channel flow status	Channel shape (undercut)	Rated	Decrease
Bank vegetation protection	% Bank cover	Measured	Decrease
	% Canopy cover	Measured	Decrease
	Disruptive pressures	Rated	Increase
Riparian vegetation zone width	Zone of influence	Rated	Decrease

Appendix I. River Aquatic Life Use Support Determination: Summaries of Metrics Used in Indexes

Four multimetric indexes comprise the river ecological assessment framework and are integrated to determine aquatic life use support. These indexes are the River Physicochemical Index (RPI), River Macroinvertebrate Index (RMI), River Diatom Index (RDI), and River Fish Index (RFI). Details describing the development of these indexes are found in the Idaho River Ecological Assessment Framework: an Integrated Approach (Grafe 2002c). The following summaries describe the metrics used in the indexes. Unlike the stream indexes, classifications are not applied in the river indexes and therefore, not discussed in these summaries.

I.1. River Physicochemical Index (RPI)

DEQ uses a water quality index developed by Oregon DEQ to interpret certain physical and chemical parameters collected on larger water bodies. The Oregon Water Quality Index (Cude, in press) has been tested and used extensively in Oregon to assess water quality conditions. DEQ has slightly modified the OWQI and therefore refers to the Idaho version as the RPI. Brandt (2000) describes the rationale for incorporating physicochemical parameters into the river bioassessment process and the additional analyses DEQ performed to determine if this index was applicable to Idaho rivers.

Table I-1 lists the eight water quality parameters comprising the RPI. Subindex scores for each variable are calculated using complex regressions for data that falls within set range and threshold scores for data outside that range (Cude in press). The individual subindexes are then averaged, using the harmonic square mean method, to produce a single index value.

Table I-1. Water Quality Parameters Used in the RPI

Temperature	Total Solids or Total Suspended Solids
Dissolved Oxygen	Ammonia + Nitrate Nitrogen
Biochemical Oxygen Demand	Total Phosphorus
pH	Fecal Coliform

I.2. River Macroinvertebrate Index (RMI)

Royer et al. (in press) developed the RMI under a four-year contract with DEQ. They applied the multimetric method described in Barbour et al. (1999) to develop the RMI. The development of the index is based on the identification of least impacted and stressed sites. Royer and Mebane (2000) describe in more detail the RMI development along with the application of the index to medium- and large-size rivers in Idaho. Royer et al. (in press) identified five significant macroinvertebrate metrics to characterize water quality condition of Idaho rivers. Table I-2 lists these metrics.

Table I-2. RMI Macroinvertebrate Metrics (Royer et al., in press)

Metric Categories	Metric	Definition	Predicted response to increasing perturbation
Richness	Number of taxa	Number of distinct taxa in the macroinvertebrate assemblage	Decrease
	Number of Ephemeroptera, Plecoptera, and Tricoptera	Number of distinct mayfly, stonefly, and caddisfly taxa in the macroinvertebrate assemblage	Decrease
Composition	Percent Elmidae	Percent of sample that is riffle beetles	Decrease
Feeding group	Percent predators	Percent of sample that is taxa which prey on other macroinvertebrates	Decrease
Diversity	Percent dominant taxon	Percent of sample in the most abundant taxa	Increase

I.3. River Diatom Index (RDI)

Periphyton, specifically diatom, indexes have been developed and applied in Montana, Oklahoma, and Kentucky. Additionally, periphyton indexes have been effectively used in Europe for river biomonitoring since the 1970s, particularly in the United Kingdom and France. Table I-3 lists the nine metrics of relative abundance and taxa richness that comprise the RDI. Fore and Grafe (2000) describe the RDI development in more detail along with supporting analysis.

Table I-3. RDI Diatom Metrics (Fore and Grafe 2000)

Metric Categories	Metric	Definition	Predicted response to increasing perturbation
Tolerance and intolerance	Percent sensitive	Percent of sample that is taxa intolerant to disturbance	Decrease
	Percent very tolerant	Percent of sample that is taxa not sensitive to disturbance	Increase
Autecological guild	Eutrophic species richness	Number of distinct taxa tolerant to nutrients, typically derived from nonorganic sources.	Increase
	Percent nitrogen heterotrophs	Percent of sample that is taxa using amino acids created by other organisms as sources of carbon and nitrogen	Increase
	Percent polysaprobic	Percent of sample that is taxa tolerant to high nutrients and low oxygen often associated with organic waste	Increase
	Alkaliphilic species richness	Number of distinct taxa tolerant to alkaline conditions	Increase
	Percent high oxygen	Percent of sample that is taxa intolerant of low oxygen often associated with organic waste decomposition or stagnate water	Decrease
Morphometric guild	Percent very motile	Percent of sample that is taxa capable of moving across unstable substrate	Increase
Individual condition	Percent deformed cells	Percent of sample that is taxa with cell deformities often associated with contamination by heavy metals	Increase

I.4. River Fish Index (RFI)

Mebane (2002) developed the RFI using the basic index of biotic integrity framework initially established by Karr et al. (1986). Mebane (2002) describes in more detail the RFI development and supporting analysis. The RFI is a quantitative multimetric index comprised of assemblage richness and composition metrics, reproductive function, abundance, and condition metrics. Table I-4 summarizes the metrics along with their expected change due to disturbance or environmental degradation.

Table I-4. RFI Fish Metrics (Mebane 2002)

Metric Categories	Metric	Definition	Predicted response to increasing perturbation
Richness and composition	Percent cold water native species	Percent of sample that is native fish species typically found in cold water streams. Excludes introduced or tolerant native fish species	Decrease
	Percent cold water individuals	Percent of sample that is individuals found in cold water streams. Includes introduced trout species	Decrease
Indicator species	Percent sensitive native individuals	Percent of sample that is native individuals sensitive to perturbations such as increased turbidity, sediment, and warmer temperatures	Decrease
	Percent tolerant individuals	Percent of sample that is individuals tolerant to disturbance	Increase
	Number of non-indigenous species	Number of distinct species occurring due to invasion or introduction	Increase
	Percent Cyprinus carpio	Percent of sample that is carp in the fish assemblage	Increase
	Percent Cottids	Percent of sample that is sculpins in the fish assemblage	Decrease

Metric Categories	Metric	Definition	Predicted response to increasing perturbation
Reproductive function	Number of salmonid age classes	Number of estimated size classes inferred from length frequency data and typical length at age relationships. Metric reflects suitability and stability of conditions for salmonid spawning, juvenile rearing, and adult salmonids.	Decrease
	Number of sculpin age classes	Number of sculpin age classes (use measured size classes to infer) reflects the availability of unembedded cobble substrate required for cavity nesters and juvenile refuge.	Decrease
Abundance	Catch per unit effort, CPUE	Number of cold water individuals per minute of single-pass electrofishing.	Decrease
Condition	Percent of fish with DELT abnormalities	Percent of fish with external deformities, eroded fins, lesions, or tumors in response to exposure to contaminated sediments or other exposure routes.	Increase

Glossary

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
305(b)	Refers to section 305 subsection "b" of the Clean Water Act. 305(b) generally describes a report of each state's water quality, and is the principle means by which EPA, congress, and the public evaluate whether US waters meet water quality standards, the progress made in maintaining and restoring water quality, and the extent of the remaining problems.
303(d)	Section 303 subsection "d" of the Clean Water Act. 303(d) requires state to develop a list of water bodies that do not meet water quality standards. This section further requires total maximum daily loads (TMDLs) be prepared for listed waters. Both the list and the TMDLs are subject to EPA approval.
A priori	Determination made before or without certain data examination; deductive. For example, macroinvertebrate data was not examined when selecting reference sites for the Stream Macroinvertebrate Index. However, other data such as habitat, chemistry, and land use were evaluated for this a priori site selection.
Ambient	General conditions in the environment. In the context of water quality, ambient waters are those representative of general conditions, not associated with episodic perturbations, or specific disturbances such as a wastewater outfall (Armantrout 1998, EPA 1996).
Aquatic	Pertaining to water. In this context, usually refers to plants or animal life living in, growing in, or adapted to water.

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
Assemblage (aquatic)	An association of interacting populations of organisms in a given water body; for example, a fish assemblage, or a benthic macroinvertebrate assemblage (also see Community) (EPA 1996).
Beneficial use	Any of the various uses of water, including, but not limited to, aquatic biota, recreation, water supply, wildlife habitat, and aesthetics.
Beneficial Use Reconnaissance Program (BURP)	Systematic biological and physical habitat surveys of water bodies in Idaho. BURP protocols address wadeable streams, rivers, lakes, and reservoirs.
Best Management Practices (BMPs)	Structural, nonstructural, and managerial techniques that are recognized to be the most effective and practical means to control nonpoint source pollutants, yet are compatible with the productive use of the resource to which they are applied.
Best professional judgment	A conclusion and/or interpretation derived by a trained and/or technically competent individual by applying interpretation and synthesizing information.
Biological integrity	1) The condition of an aquatic community inhabiting unimpaired water bodies of a specified habitat as measured by an evaluation of multiple attributes of the aquatic biota (EPA 1996). 2) The ability of an aquatic ecosystem, to support and maintain a balanced, integrated, adaptive community of organisms having a species composition, diversity, and functional organization comparable to the natural habitats of a region (Karr 1991).
Biota	The animal and plant life of a given region.
Biotic community	A naturally occurring assemblage of plants and animals that live in the same environment and are mutually sustaining and interdependent.

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
Clean Water Act	The Federal Pollution Control Act (PL92-500, commonly known as the Clean Water Act), as last reauthorized by the Water Quality Act of 1987 (PL100-4), establishes a process for states to develop information on and control the quality of the nation's water resources.
Coliform Bacteria	A group of bacteria found in the intestines of warm-blooded animals (including humans), plants, soil, air, and water. Fecal coliform are a specific class of bacteria, which only inhabit the intestines of warm-blooded animals. The presence of coliform is an indication that the water is polluted and may contain pathogenic organisms (also see Fecal Coliform Bacteria).
Community (aquatic)	An association of interacting assemblages in a given water body; the biotic component of an ecosystem (also see Assemblage) (EPA 1996).
Criteria	Numeric or descriptive factors taken into account in setting standards for various pollutants. These factors are used to determine limits on allowable concentration levels, and to limit the number of violations per year. EPA develops criteria guidance; states establish criteria.
Designated uses	Those water uses identified in state water quality standards that must be achieved and maintained as required under the Clean Water Act.
Discharge	The amount of water flowing in the stream channel at the time of measurement. Usually expressed as cubic feet per second (cfs).
Dissolved oxygen (DO)	The oxygen dissolved in water. DO is vital to fish and other aquatic life and helps prevent odors. DO levels are considered an important indicator of a water body's ability to support desirable aquatic life.
Disturbance	Any event or series of events that disrupt ecosystem, community, or population structure and alter the physical environment.

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
Duration	The period of time (averaging period) over which the in-stream concentration is averaged for comparison with criteria concentrations. This specification limits the duration of concentrations above the criteria.
E. coli	Escherichia Coli, is a group of bacteria that are a subspecies of coliform bacteria. Most E. coli are essential to the healthy life of all warm-blooded animals, including humans.
Ecological indicator	A characteristic of an ecosystem that is related to, or derived from, a measure of a biotic or abiotic variable that can provide quantitative information on ecological structure and function. An indicator can contribute to a measure of integrity and sustainability. Ecological indicators are often used within the multimetric index framework.
Ecological integrity	1) A living system exhibits integrity if, when subjected to disturbance, it sustains and organizes self-correcting ability to recover toward a biomass end-state that is normal for that system. 2) The condition of an unimpaired ecosystem as measured by combined chemical, physical (including habitat), and biological attributes (EPA 1996).
Ecosystem	The interacting system of a biological community and its non-living environmental surroundings.
Endangered species	Animals, birds, fish, plants, or other living organisms threatened with extinction by anthropogenic (human-caused) or other natural changes in their environment. Requirements for declaring a species endangered are contained in the Endangered Species Act.
Ephemeral stream	A stream or portion of a stream that flows only in direct response to precipitation. It receives little or no water from springs and no long continued supply from melting snow or other sources. Its channel is at all times above the water table. (*Dictionary of Geologic Terms*, American Geologic Institute, 1962).

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
Eutrophication	(1) Natural process of maturing (aging) in a body of water. (2) Natural and human-influenced process of enrichment with nutrients, especially nitrogen and phosphorus, leading to an increased production of organic matter.
Exceedance	Above pollutant levels permitted by environmental protection standards. Violation of Idaho water quality standards may occur based on DEQ policy (see Section 5).
Existing beneficial use or existing use	A beneficial use present in waters on or after November 28, 1975, whether or not the use is designated for those waters in the *Water Quality Standards and Wastewater Treatment Requirements*.
Exotic species	A species that is not native indigenous to a region.
Extrapolation	Estimation of unknown values by extending or projecting from known values.
Fecal coliform bacteria	Bacteria found in the intestinal tracts all warm-blooded animals of mammals. Their presence in water is an indicator of pollution and possible contamination by pathogens (also see Coliform).
Fixed-location monitoring	Sampling of an environmental or ambient medium for pollutant concentrations at one location continuously or repeatedly.
Frequency	The number of times air event occurs over a fixed time interval.
Fully supporting	In compliance with water quality standards and criteria, and meeting the reference conditions for all designated and existing beneficial uses as determined through the WBAG.
Fully supporting of cold water aquatic life	Reliable data indicate functioning, sustainable cold water biological assemblages (e.g., fish, macroinvertebrates, or algae), none of which have been modified significantly beyond the natural range of reference conditions (EPA 1995).

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
GIS	Geographic Information System, a georeferenced database.
Grab sample	A single sample collected at a particular time and place. May represent the composition of the water only at that time and place.
Ground water	The supply of fresh water found beneath the earth's surface.
Habitat	The place where a population (e.g., human, animal, plant, microorganism) lives and its surroundings, both living and non-living.
Human made	Relating to or resulting from the influence of human beings on nature (anthropogenic)
Hydrologic Unit Code (HUC)	A watershed numbering system developed by the U.S. Geological Survey.
Hydrology	The science dealing with the properties, distribution, and circulation of water.
Instantaneous	A concentration of a substance measured at any moment (instant) in time.
Intergravel dissolved oxygen	The concentrations of dissolved oxygen in the spawning gravel. Considerations for determining spawning gravel include species, water depth, velocity, and substrate.

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
Intermittent stream	1) A stream (in contact with the ground water table) that flows only part of the year, such as when the ground water table is high or when it receives water from springs or from some surface source such as melting snow in mountainous areas. It ceases to flow above the streambed when losses from evaporation or seepage exceed the available stream flow. 2) A stream that has a period of zero flow for at least one week during most years. A stream with a 7Q2 of less than 0.1 cfs is considered intermittent for steady-state waste load allocation modeling. Streams with perennial pools that create aquatic life uses are not intermittent (Idaho Water Quality Standards and Wastewater Treatment Requirements, IDAPA 58.01.02.51.).
Interstate waters	Waters that flow across or form part of state or international boundaries.
Lotic	Aquatic system with flowing water such as a brook, stream, or river where the net flow of water is from the headwaters to the mouth.
Macroinvertebrate	An invertebrate animal (without backbone) large enough to be seen without magnification and retained by a 0.595 mm (U.S.#30) screen.
Magnitude	How much of a pollutant, expressed as a concentration, is allowable.
Metric	One discrete measure of an ecological indicator (e.g., number of distinct taxon).
Monitoring	Periodic or continuous surveillance or testing to determine the level of compliance with statutory requirements and/or pollutant levels in various media or in humans, plants, and animals.
Natural condition	A condition without human-caused disruptions.

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
Non-point sources	Diffuse pollution sources (i.e., without a single point of origin or not introduced into a receiving stream from a specific outlet). The pollutants are generally carried off the land by storm water. Common non-point sources are agriculture, forestry, urban, mining, construction, dams, channels, land disposal, and saltwater intrusion.
Not assessed	A concept and an assessment category describing water bodies that have been looked at, but are missing critical information needed to complete an assessment.
Not fully supporting	Not in compliance with water quality standards or criteria, or not meeting reference conditions for each beneficial use as determined through the WBAG.
Not fully supporting cold water aquatic life	At least one biological assemblage has been significantly modified beyond the natural range of its reference condition (EPA 1995).
Nutrient	Any substance assimilated by living things that promote growth. In water, the term is generally applied to nitrogen and phosphorus, but is also applied to other essential and trace elements and organic carbon.
Parameter	A variable, measurable property whose value is a determinant of the characteristics of a system; e.g., temperature, pressure, and density are parameters of the atmosphere.
Pathogens	Microorganisms (e.g., bacteria, viruses, or parasites) that can cause disease in humans, animals and plants.
Periphyton	Attached microflora growing on the bottom, or on other submerged substrates, including higher plants. Epilithic periphyton is flora growing on the surface of rock or stones. Diatoms are a type of periphyton.

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
Pesticide	Substances or mixtures of substances intended for preventing, destroying, repelling, or mitigating any pest. Also, any substance or mixture intended for use as a plant regulator, defoliant, or desiccant.
pH	pH (pronounced as separate letters) is an expression of the intensity of the basic or acidic condition of a liquid. Mathematically, pH is the logarithm (base 10) of the reciprocal of the hydrogen ion concentration, [H+]. pH= Log (I/[H+]). The pH may range from 0 to 14, where 0 is most acidic, 14 most basic, and 7 neutral.
Phosphorus	An essential chemical food element that can contribute to the eutrophication of lakes and other water bodies. Increased phosphorus levels result from discharge of phosphorus-containing materials into surface waters.
Physicochemical	In the context of bioassessment, the term is commonly used to mean the physical and chemical factors of the water column that relate to aquatic biota. Examples in bioassessment usage include saturation of dissolved gases, temperature, pH, conductivity, dissolved or suspended solids, forms of nitrogen, and phosphorus. This term is used interchangeably with the term physical/chemical or physiochemical.
Point source	A discrete location or fixed facility from which pollutants are discharged; any single identifiable source of pollution.
Pollutant	Generally, any substance introduced into the environment that adversely affects the usefulness of a resource or the health of humans, animals, or ecosystems.

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
Pollution	A concept that encompasses the presence of a substance in the environment that because of its chemical composition or quantity prevents the functioning of natural processes and produces undesirable environmental and health effects as well as the human-made or human-induced alteration of the physical, biological, chemical, and radiological integrity of water and other media.
Population	A group of interbreeding organisms occupying a particular space; the number of humans or other living creatures in a designated area.
Protocol	A series of formal steps for conducting a test or survey.
Qualitative	Descriptive of kind, type, or direction, as opposed to size, magnitude, or degree.
Quality assurance (QA)	A program organized and designed to provide accurate and precise results. Included are selection of proper technical methods, tests, or laboratory procedures; sample collection and preservation; selection of limits; evaluation of data; quality control; and qualifications and training of personnel. Its goal is to assure the data provided are of the quality needed and claimed (Rand 1995, EPA 1996).
Quality control (QC)	Routine application of specific actions required to provide information for the quality assurance program. Included are standardization, calibration, and replicates. Quality control is implemented at the field or bench level (Rand 1995, EPA 1996).
Quantitative	Descriptive of size, magnitude, or degree.
Reconnaissance	An exploratory or preliminary survey of an area.
Reference	A physical or chemical quantity whose value is known, and thus is used to calibrate or standardize instruments.

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
Reference condition	(1) A condition that fully supports applicable beneficial uses with little affect from human activity and represents the highest level of support attainable. (2) A benchmark for populations of aquatic ecosystems used to describe desired conditions in a biological assessment and acceptable or unacceptable departures from them. The reference condition can be determined through examining regional reference sites, historical conditions, quantitative models, and expert judgment (Hughes 1995).
Reference site	A specific locality on a water body that is minimally impaired and is representative of the expected ecological integrity of other localities on the same water body or nearby water bodies (EPA 1996).
Representative sample	A portion of material or water that is similar in content and consistency as possible to that in the larger body of material or water being sampled.
River	Large, natural, or human-modified stream that flows in a defined course or channel, or a series of diverging and converging channels. See Section 2 for water body size criteria.
Salmonids	Members of the family *Salmonidae*, which includes trout, salmon, and whitefishes. Salmonids that have been reported to occur in Idaho include trout (bull, cutthroat, rainbow, redband, steelhead, brook, brown, golden, and lake), salmon (Chinook, coho, Kokanee, and sockeye) whitefishes, (Bear Lake, mountain, pygmy, lake, Bonneville whitefish and Bonneville cisco), and Arctic grayling. These include both native and introduced species.
Sediments	Deposits of fragmented materials from weathered rocks and organic material that are suspended in, transported by, and eventually deposited by water or air.
Species	1) A reproductively isolated aggregate of interbreeding organisms having common attributes and usually designated by a common name. 2) An organism belonging to such a category.

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
Spring	Ground water seeping out of the earth where the water table intersects the ground surface.
Stenothermal	Unable to tolerate a wide temperature range.
Stratification	DEQ classification method used to characterize comparable segments within each water body identified in the WBID system. DEQ uses land use and stream order to stratify water bodies.
Stream	A natural water course containing flowing water, at least part of the year, together with dissolved and suspended materials, that normally supports communities of plants and animals within the channel and the riparian vegetation zone. See Section 2 for water body size criteria.
Stream order	Hierarchical ordering of streams based on the degree of branching. A first-order stream is an unforked or unbranched stream. Two first-order streams flow together to form a second-order stream, two second-order streams combine to make a third-order stream, etc. (Strahler 1957)
Stressors	Physical, chemical, or biological entities that can induce adverse effects on ecosystems or human health.
Surface runoff	Precipitation, snow melt, or irrigation water in excess of what can infiltrate the soil surface and be stored in small surface depressions; a major transporter of non-point source pollutants in rivers, streams, and lakes.
Surface water	All water naturally open to the atmosphere (rivers, lakes, reservoirs, streams, impoundments, seas, estuaries, etc.) and all springs, wells, or other collectors that are directly influenced by surface water.
Taxon	Any formal taxonomic unit or category of organisms (e.g., species, genus, family, order). The plural of taxon is taxa (Armantrout 1998).

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
TMDL	An acronym that stands for total maximum daily load. A TMDL is an estimation of the maximum pollutant amount that can be present in a water body and still allow that water body to meet water quality standards (40 CFR Part 130). In common usage, a TMDL also refers to the written document that contains the statement of loads and supporting analyses, often incorporating TMDLs for several water bodies and/or pollutants within a given watershed.
Toxic pollutants	Materials that cause death, disease, or birth defects in organisms that ingest or absorb them. The quantities and exposures necessary to cause these effects can vary widely.
Turbidity	A measurement used to indicate the clarity of water. Technically, turbidity is an optical property of water based on the amount of light scattered by suspended particles. Turbidity cannot be directly equated to suspended solids because white particles scatter more light than dark-colored particles and many small particles will scatter more light than an equivalent weight large particle.
Water body	A homogeneous classification that can be assigned to rivers, lakes, estuaries, coastlines, or other water features.
Water quality	A term used to describe the biological, chemical, and physical characteristics of water with respect to its suitability for a beneficial use.
Water quality criteria	Levels of water quality expected to render a body of water suitable for its designated use. Criteria are based on specific levels of pollutants that would make the water harmful if used for drinking, swimming, farming, or industrial processes.
Water quality standards	State-adopted and EPA-approved ambient standards for water bodies. The standards prescribe the use of the water body and establish the water quality criteria that must be met to protect designated uses.

Note: This glossary is intended to define terms within the context of the WBAG. Unless otherwise cited, these working definitions were prepared by DEQ.

Term	Definition
Watershed	The land area that drains into a stream. An area of land that contributes runoff to one specific delivery point; large watersheds may be composed of several smaller "subwatersheds," each of which contributes runoff to different locations that ultimately combine at a common delivery point.
WBID	Water body identification number; a number that identifies a water body, and correlates to Idaho Water Quality Standards and GIS information.
Wetland	An area that is saturated by surface or ground water with vegetation adapted for life under those soil conditions, as swamps, bogs, fens, marshes, and estuaries.
